Forest Statistics for Michigan's Eastern Upper Peninsula Unit, 1993

Thomas L. Schmidt

This report includes the most commonly used U.S. Department of Agriculture, Forest Service, Forest Inventory and Analysis (FIA) statistics. Additional forest resource data can be provided to interested users. Persons requesting additional information from the raw inventory data are expected to pay the retrieval costs. These costs range from less than \$100 for a relatively simple request to more than \$2,000 for a complex retrieval involving the services of a Forest Inventory and Analysis computer programmer. Requests will be filled so as to minimize the impact on the Forest Inventory and Analysis Work Unit.

Requests for information may be directed to:

FOREWORD

Forest Inventory and Analysis (FIA) is a continuing endeavor as mandated by the Renewable Resources Research Act of 1978. Prior inventories were mandated by the McSweeney-McNary Forest Research Act of 1928. The objective of FIA is to periodically inventory the Nation's forest land to determine its extent, condition, and volume of timber, growth, and removals. Up-to-date resource information is essential to frame forest policies and programs. USDA Forest Service regional experiment stations are responsible for conducting these inventories and publishing summary reports for individual States. The North Central Forest Experiment Station is responsible for forest inventory and analysis in Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, South Dakota, and Wisconsin.

Fieldwork for the fifth forest inventory of Michigan's Eastern Upper Peninsula Unit forest inventory was begun in April of 1991 and completed in September of 1992. Reports of the four previous inventories of Michigan's timber resource are dated 1935, 1955, 1966, and 1980.

More accurate survey information was obtained during this survey than otherwise would have been feasible because of intensified field sampling. Sampling intensity was increased from a single intensity level to a triple intensity level, providing reliable data at a county level. Such sampling was made possible through the cooperation, assistance, and additional funding provided by the State of Michigan and Michigan forest industries and associations. To aid in determining current timber removals, the Michigan Department of Natural Resources (MiDNR) also surveyed primary wood-using plants in the State. Aerial photographs used were black and white, infrared taken in 1986 at a scale of 1:15,840 (nominal). These photographs were purchased by the MiDNR and loaned to the Forest Service.

Forest Statistics For Michigan's Eastern Upper Peninsula Unit, 1993

Thomas L. Schmidt

HIGHLIGHTS

NOTE: Data from new forest inventories are often compared with data from earlier inventories to determine trends in forest resources. However, for the comparisons to be valid, the procedures used in the two inventories must be similar. As a result of our ongoing efforts to improve the inventory's efficiency and reliability, we have made several changes in procedures and definitions since the last Michigan inventory in 1980. Because some of these changes make it inappropriate to directly compare the 1993 data with those published for 1980, data from the 1980 inventory have been re-processed using the current procedures. Please refer to the appendix section labeled "Comparing the Fifth Inventory of Michigan's Eastern Upper Peninsula With the Fourth Inventory" for more details.

All area and volume data and tables were based on what existed as of January 1, 1993, in the Eastern Upper Peninsula of Michigan. The time period used for growth, removals, and mortality was January 1, 1980, to December 31, 1992. **The data in this report are subject to change when inventory data for the entire State have been compiled. It is expected, however, that any such changes will be minor.**

Thomas L. Schmidt, Research Forester, received a bachelor's degree in forest management in 1976 and a master's degree in forestry/land-use planning in 1981 from the University of Missouri-Columbia. He received his Ph.D in agronomy/ecology from the University of Nebraska-Lincoln in 1991. He joined the Forest Service in 1992 as a Resource Analyst in the Forest Inventory and Analysis Unit of the North Central Forest Experiment Station, located in St. Paul, Minnesota.

General

The Eastern Upper Peninsula of Michigan (fig. 1) is comprised of seven counties. Historically, the forest resource has been one of the principal economic, social, and environmental factors in this area. Forest products from this region range from bathroom tissue to construction lumber, and are used throughout the world. The forest resource provides recreational and scenic values of growing economic importance. Thus, the status and condition of Michigan's Eastern Upper Peninsula's forest resource are of utmost concern on a local, national, and international level.

The Upper Peninsula forest resource was exposed to heavy cutting followed by widespread uncontrolled fires, in the late 1800's. With fire protection well established by the 1920's, the forest quickly responded and re-established itself. The forest reached seedling and sapling size by 1935 and poletimber size by 1955 (Chase and Pfeifer 1970). The result is a forest resource that is currently well stocked with large size classes. The following are a few major highlights from the 1993 inventory of the Eastern Upper Peninsula Survey Unit.

Area

- Forest land accounted for more than 3,973,100 acres in 1993, 80 percent of the total land area. Forest land is comprised of timberland (77 percent of all land area), productive-reserved forest land (2 percent of all land area), and unproductive forest land (1 percent of all land area). The remaining land area is comprised of cropland, pasture, and developed land such as roads and towns.

Figure 1.—Eastern Upper Peninsula Survey Unit, 1993.

- The total area of forest land declined by an average of 4,500 acres per year between 1980 and 1993—from 4,031,600 acres in 1980 to 3,973,100 acres in 1993. This decline represented a decrease in the area of forest land of 0.1 percent per year.
- While total acreage of forest land declined slightly, total acreage of timberland increased slightly. There were 3,810,000 acres of timberland in 1993, a gain of 8,400 acres since 1980. The increase in timberland occurred as marginal forest lands, previously classified as unproductive, were classified in 1993 as being productive enough to be timberland.
- As in all past inventories, Chippewa County had the largest area of timberland in the Eastern Upper Peninsula—704,800 acres in 1993 (fig. 2).
- Alger County had the highest percentage of land in forests (90 percent), while Schoolcraft County had the lowest percentage of land occupied by forest (72 percent).
- Individuals and farmers were the largest class of timberland owners in 1993, with 32 percent of the total timberland (fig. 3).

Figure 2.—Area of timberland, by county, Eastern Upper Peninsula, 1993.

Figure 3.—Area of timberland by ownership class, Eastern Upper Peninsula, 1993.

- Although hardwood forest types dominated in terms of acreages occupied in 1993, there were more live softwood trees on timberland (1.4 billion) than hardwoods (1.3 billion).
- As in previous inventories, maple-birch was the dominant forest type with more than 33 percent of all timberland. Maple-birch had twice as many acres as the second largest forest type, northern white-cedar (fig. 4).
- Almost 41 percent of all timberland was in the sawtimber stand-size class in 1993—an increase of 13 percent since 1980. While total area of timberland has declined, the nonstocked area has decreased from the 1930's (fig. 5). [Note: data from 1935, 1955, and 1966 have not been adjusted to reflect current inventory methods and definitions (Cunningham *et al.* 1936, Findell *et al.* 1960, Chase and Pfeifer 1970). Thus, comparisons between inventory results only reflect general trends].

Volume

- Total growing-stock volume on timberland rose to 5.2 billion cubic feet in 1993 from 4.1 billion cubic feet in 1980—a gain of almost 25 percent. The volume averaged more than 1,353 cubic feet per acre of timberland in 1993 compared to 1,089 cubic feet per acre in 1980.

Figure 4.—Area of timberland, by forest type, Eastern Upper Peninsula, 1993.

- Softwoods accounted for more growing-stock volume than hardwoods for all trees less than 8.9 inches in diameter at breast height (d.b.h. = 4.5 feet above ground level). The greater volumes in the smaller size classes reflect the heavier stocking rates at younger ages often found in softwood stands.

Figure 5.—Area of timberland by stand-size class, for selected inventory years for the Eastern Upper Peninsula.

- Softwood growing-stock volume totaled more than 2.3 billion cubic feet in 1993. Figure 6 shows the softwood growing-stock volume by species group.

Figure 6.—Growing-stock volume for softwoods, by species groups, Eastern Upper Peninsula, 1993.

- Softwoods also accounted for more growing-stock volume in trees greater than 21 inches d.b.h. because of older white pine and hemlock. White pine alone accounted for 32 percent of all growing-stock volume greater than 21 inches d.b.h., but it accounted for only 4 percent of the total net volume.
- Hardwood growing-stock volume accounted for more than 2.8 billion cubic feet in 1993. Figure 7 shows the hardwood growing-stock volume by species group.
- All four major species groups increased in volume from 1980 to 1993 (fig. 8). The greatest proportional increase was in pine, which increased 52 percent, followed by hard hardwoods (32 percent), other softwoods (20 percent), and soft hardwoods (16 percent).
- Growing-stock volume increased between 1980 and 1993 for all forest types except white spruce, black spruce, and paper birch.

Figure 7.—Growing-stock volume for hardwoods by species groups, Eastern Upper Peninsula, 1993.

- Individuals and farmers, State, and National Forest owners accounted for more than 75 percent of all growing-stock volume.
- Hard maple accounted for 31 percent of all hardwood volume graded as the best quality tree grade.

Figure 8.—Net volume of growing stock by major species groups, Eastern Upper Peninsula, 1980 and 1993.

Growth

- Average annual net growth on timberland was 132.6 million cubic feet for growing stock from 1980 through 1992. The Eastern Upper Peninsula of Michigan had an average net growth of 35 cubic feet per acre.
- Annual sawtimber net growth averaged 472.6 million board feet on timberland from 1980 through 1992. On average, every acre of timberland in the Unit grew more than 124 board feet of sawtimber each year.
- For growing stock, softwoods accounted for 64 million cubic feet (48 percent) of average annual net growth between 1980 and 1992. Hardwoods accounted for more than 68 million cubic feet (52 percent).
- The red pine forest type averaged the greatest annual net growth per acre at 71 cubic feet; tamarack averaged the lowest, only 16 cubic feet per acre per year (fig. 9). Tamarack, black spruce, and northern white-cedar (swamp conifers) had low growth rates primarily because of the low growth potential of the sites where they are found. These swamp conifers primarily occupy sites where excess water inhibits their growth.

- Average annual net growth of growing stock between 1980 and 1992 was 2.6 percent of inventory. If current improved techniques of measuring growth had been used in 1980, net growth in 1980 would probably have ranged from 2.5 to 2.7 percent of total volume, instead of the 3.3 percent reported.

Removals

- An average of 52.5 million cubic feet of growing stock and 142.4 million board feet of sawtimber were removed each year between inventories, both well below the annual growth rate.
- From 1980 to 1992, the highest total softwood sawtimber removals were from the white spruce, white pine, hemlock, and northern white-cedar species groups. Highest total hardwood sawtimber removals were for beech, hard maple, and quaking aspen.
- State-owned lands were first in terms of growing-stock removals of pine, with an average of more than 3.5 million cubic feet removed annually between 1980 and 1992.
- Individual owners accounted for 29 percent of all sawtimber removals between 1980 and 1992.

Figure 9.—Average net annual growth per acre, by forest type, Eastern Upper Peninsula, 1980 - 1992.

- Growing-stock removals on timberland averaged almost 40 percent of growing-stock growth from 1980 through 1992—52.5 million cubic feet of removals compared to 132.6 million cubic feet of growth.
- Growing-stock removals on timberland averaged 13.8 cubic feet per acre, representing about 1 percent of the total volume per acre.

Mortality

- Growing-stock mortality averaged more than 42 million cubic feet each year between inventories. Sawtimber mortality averaged more than 88 million board feet during this period. These totals represent an annual loss of less than 1 percent of all volumes.
- From 1980 through 1992, red pine, white pine, northern white-cedar, select red oak,

beech, and hard maple had the lowest levels of growing-stock mortality as a percent of their total volume. All these species groups had less than 0.2 percent of their total growing-stock volume reported as mortality per year.

- Balsam fir and quaking aspen species groups accounted for more than 37 percent of all mortality.
- Balsam fir, white spruce, balsam poplar, and quaking aspen had more than 48 percent of all sawtimber mortality between 1980 and 1992.
- As a percent of sawtimber inventory volume, red pine, white pine, select red oak, beech, hard maple, and white and green ash species groups had less than 0.2 percent in mortality each year from 1980 to 1992.

APPENDIX

ACCURACY OF THE SURVEY

Forest Inventory and Analysis (FIA) information is based on a sampling procedure designed to provide reliable statistics at the State and Survey Unit levels. Consequently, the reported figures are estimates only. A measure of reliability of these figures is given by sampling errors. The level of sampling error utilized by FIA means the chances are two out of three that if a 100-percent inventory had been taken, using the same methods, the results would have been within the limits indicated.

For example, the estimated growing-stock volume in the Eastern Upper Peninsula Unit in Michigan in 1993, 5,156.4 million cubic feet, has a sampling error of ± 1.33 percent (± 68.6 million cubic feet). Based on this sampling error, growing-stock volume from a 100-percent inventory would be expected to fall between 5,087.8 and 5,225.0 million cubic feet ($5,156.4 \pm 68.6$), there being a one in three chance that this is not the case. The following tabulation shows the sampling errors for Michigan's Eastern Upper Peninsula Forest Inventory:

Item	Unit totals	Sampling error
Growing stock	Million cubic feet	Percent
Volume (1993)	5,156.4	1.33
Average annual growth (1980-1992)	132.6	2.06
Average annual removals (1980 - 1992)	52.5	7.02
Sawtimber	Million board feet	
Volume (1993)	13,399.1	1.97
Average annual growth (1980-1992)	472.6	2.34
Average annual removals (1980 - 1992)	142.4	7.81
Timberland	Thousand acres	
area (1993)	3,810.0	0.72

As survey data are broken down into sections smaller than Survey Unit totals, the sampling error increases. For example, the sampling error for timberland area in a particular county is higher than that for total timberland area in the Unit. This tabulation shows the sampling errors for Unit totals. To estimate sampling error for data smaller than Unit totals, use the following formula:

$$E = \frac{(SE) \sqrt{(\text{Unit total area or volume})}}{\sqrt{(\text{Volume or area smaller than Unit total})}}$$

where:

E = sampling error in percent

SE= Unit total error for area or volume

For example, to compute the error on the area of timberland in the maple-birch type for the Unit, proceed as follows:

1. Total area of timberland in the maple-birch forest type in the Unit from table 3 = 1,263,100 acres;
2. Total area of all timberland in the Unit from table 3 = 3,810,000 acres;
3. Unit total error for timberland area from the above tabulation = 0.72 percent.

Using the above formula:

$$E = \frac{(0.72) \sqrt{(3,810,000)}}{\sqrt{(1,263,100)}} = \pm 1.25 \text{ percent.}$$

County Data

A standard FIA inventory is designed to provide sampling errors of no more than 3 percent per million acres of timberland. Thus, this Unit's 3.81 million acres of timberland would require a sampling error of 1.54 percent to meet national FIA standards. The State of Michigan funded the collection of additional field data to substantially reduce sampling error. The goal was to provide a sampling error of less than 10 percent for total timberland area by county. The sampling error within a county depends on county size and total area of timberland. To provide for a sampling error of less than 10 percent for total timberland area by county, a minimum acreage level of about 35,000 acres was required. The heavily forested nature of the seven counties in the Eastern Upper Peninsula, in combination with the intensified sample size provided by the Michigan Department of Natural Resources (MiDNR), resulted in sampling errors for each county of well below 5 percent.

COMPARING THE FIFTH INVENTORY OF THE EASTERN UPPER PENINSULA WITH THE FOURTH INVENTORY

A new volume estimation procedure was developed for the Lake States. We used this procedure to compute the 1993 volumes and to re-compute the 1980 volume for growth calculations. Although the adjustment will differ by species, the re-computed 1980 volumes will generally be greater than those shown in the original 1980 report.

Past surveys used only growing-stock trees to determine stand-size class. Current survey procedures require that stand-size class be determined on the basis of all live trees. Therefore, direct comparisons of current inventory data to old inventory data by stand-size class may be misleading.

The basic building block for estimating forest area and timber volume has been changed from the Survey Unit (as utilized during the 1980 inventory) to the county (current methodology). In the past, statistics were developed at the Unit level and prorated back to the county on the basis of photo-interpretation results. Direct development of county-level data helps users interested in more precise local data, but can make the outcome of comparisons with past estimates uncertain.

SURVEY PROCEDURES

The 1993 survey of Michigan's Eastern Upper Peninsula used a growth model-enhanced, two-phase sample design. Using this sampling scheme and associated estimators is similar to sampling with partial replacement, in that a set of randomly located plots is available for remeasurement and a random set of new plots is established and measured. A significant feature of the new design is stratification for disturbance on the old sample and use of a growth model to improve regression estimates made on old undisturbed forest plots (fig. 10). Detailed descriptions of the sampling and estimation procedures are presented by Hansen (1990). The growth model used in the survey design for Michigan's Eastern Upper Peninsula was the Lake States Stand and Tree Evaluation and Modeling System (STEMS) (Belcher *et al.* 1982).

Figure 10.—Overview of the sample design for Michigan's Eastern Upper Peninsula 1993 survey.

Major Steps in the New Survey Design

1. Aerial photography (Phase 1)

In this phase, two sets of random points were located on current aerial photographs. The first set was new photo plots and the second set was relocated, old ground plot locations from the 1980 inventory. Locations of the plots used in the 1980 inventory were transferred to the new photographs. The photographs were then assembled into township mosaics, and a systematic grid of 121 one-acre photo plots (each plot representing approximately 190.4 acres) was overlaid on each township mosaic. Each photo plot was examined by aerial photogrammetrists and classified stereoscopically as to its land use. If trees were present, forest type and stand-size/density classes were recorded. All of the 1980 ground plot locations were also examined for disturbance (logging, fire, catastrophic mortality, etc.). After this examination, all the old "disturbed" sample locations and one-third of the old "undisturbed" forested plots were sent to the field for survey crews to verify the photo classification and to take further measurements. All photo plot locations for the 1993 inventory were examined and classified as shown in the following tabulation.

Photo land class	Photo plots
Timberland	19,937
Reserved forest land	325
Other forest land	9
Questionable	958
Nonforest with trees	681
Nonforest without trees	4,202
Water	693
All classes	26,805

2. Plot measurements (Phase 2)

On plots classified as timberland, wooded pasture, or windbreak (at least 120 feet wide), a ground plot was established, remeasured, or modeled. Old plots sent to the field for remeasurement that could not be relocated were replaced with a new plot at the approximate location of the old one. Each ground plot consisted of a 10-point cluster covering 1 acre. At each point, trees 5.0 inches or more in d.b.h. were sampled on a 37.5 basal area factor variable-radius plot, and trees less than 5.0 inches d.b.h. were sampled on a 1/300-acre fixed-radius plot. The measurement procedure for both the new and old sample locations was as follows:

a. New inventory plots

A random sample of the new photo plots was selected for field measurement. Ground plots were established, and measures of current

classification such as land use, forest type, and ownership, as well as size and condition of all trees on the plot, were recorded. These locations were monumented for future remeasurement.

b. Old inventory plots

These plots were originally established, monumented, and measured as part of the 1980 field inventory. Procedures for these old plots were different from those for the new plots. Old plots were classed as "undisturbed" or "disturbed" in the aerial photo phase of the sampling process. All disturbed plots and a one-third sample of the undisturbed forested plots were remeasured to obtain estimates of current condition and changes since the last inventory. All trees measured on these plots in 1980 were remeasured or otherwise accounted for, and all new trees were identified and measured.

All sample plots that were forested at the time of the 1980 inventory and determined to be undisturbed until the 1993 inventory were projected to the current time (1993) using STEMS. This procedure gives projected estimates of current volume and growth for undisturbed plots. Comparison of the projected and observed values on the one-third sample of the undisturbed forest plots that were remeasured provided local calibration data to adjust the projected values of the undisturbed plots that were not remeasured. The adjustment procedure is a modified version of the method described by Smith (1983).

Undisturbed forested plots that were not remeasured played a crucial role in the new survey design. These plots, after careful comparison of past and current aerial photography, were determined to be undisturbed and had conditions that could be simulated by STEMS. The STEMS growth model was used to "grow" the old plot and tree data to produce an estimate of current data. Thus, these plots were treated as ground plots, even though they were never visited. The plot record for each modeled plot was sent to the field for verification of current ownership information.

All old plots classified as disturbed were sent to the field for remeasurement to assess and verify changes since the last inventory. Disturbance referred to any change on a plot that was detected on aerial photos and that the STEMS growth processor could not predict, such as catastrophic mortality, cutting, seedling stands, and/or land use change.

The estimation procedure for computing statistics from this sampling design was more complicated than the simple two-phase estimation procedure used in the past. In fact, this procedure yielded two independent samples, one coming from the new photo points and the other from the old photo points that were remeasured or modeled. The following tabulation summarizes the distribution of all ground plots for the new inventory design by type of plot:

Ground land use class	Old plots remeasured	Old plots updated	New plots	Total plots
Timberland	991	1,080	526	2,597
Reserved forest land	14	5	72	91
Other forest land	25	0	10	35
Nonforest with trees	43	23	23	89
Nonforest without trees	62	404	144	610
Water	9	65	23	97
Total	1,144	1,577	798	3,519

3. Area estimates

Area estimates were made using two-phase estimation methods. In this type of estimation, a preliminary estimate of area by land use is made from the aerial photographs (Phase 1) and corrected by the plot measurements (Phase 2). A complete description of this estimation method is presented by Loetsch and Haller (1964). All area estimates were based on what existed as of January 1, 1993, in the Eastern Upper Peninsula of Michigan.

4. Volume estimates

Estimates of volume per acre were made from the trees measured or modeled on the 10-point plots. Estimates of volume per acre were multiplied by the area estimates to obtain estimates of total volume. Volume estimates were based on what existed as of January 1, 1993, in the Eastern Upper Peninsula of Michigan. Net cubic foot volumes were based on a modification of the method presented by Hahn (1984) for use in the Lake States. For the Eastern Upper Peninsula inventory, the merchantable height equation presented was used in conjunction with Hahn's Board Foot Volume Equation (adapted from Stone's equation—Hahn 1984) to estimate gross volume. This estimate was then corrected by species for variation in bark and cull volume to yield an estimate of net volume (Hahn 1984).

The Forest Service reports all board foot volume in International 1/4-inch rule. In Michigan, the Scribner log rule is commonly used. Scribner log rule conversion factors were derived from full tree measurements taken throughout the Lake States (Michigan, Wisconsin, and Minnesota) and an equation developed by Wiant and Castenaeda (1977). Factors, or multipliers, that can be used to convert board foot International volumes to the Scribner rule are shown in the following tabulation:

D.b.h. (inches)	Scribner rule conversion factor	
	Softwoods	Hardwoods
9.0-10.9	0.7830	—
11.0-12.9	.8287	0.8317
13.0-14.9	.8577	.8611
15.0-16.9	.8784	.8827
17.0-18.9	.8945	.8999
19.0-20.9	.9079	.9132
21.0-22.9	.9168	.9239
23.0-24.9	.9240	.9325
25.0-26.9	.9299	.9396
27.0-28.9	.9321	.9454
29.0+	.9357	.9544

5. Growth and mortality estimates

On remeasured plots, estimates of growth and mortality per acre come from the remeasured diameters of trees and from observation of trees that died between inventories. Growth reported as the average net annual growth between the two inventories (1980 and 1992) was computed from data on remeasurement plots and modeled plots using methods presented by VanDeusen *et al.* (1986). Mortality was also reported as average annual for the remeasurement period. On new plots, where trees were not remeasured, estimates of growth and mortality were obtained by using STEMS to project the growth and mortality of trees for 1 year. Growth and mortality estimates for old undisturbed plots that were updated were derived in the same manner as remeasured plots. The STEMS growth model was adjusted to meet local conditions, using data from the undisturbed remeasurement plots. As with volume, total growth and mortality estimates were obtained by multiplying the per acre estimates by area estimates. Current annual growth for 1992 was computed by using the adjusted STEMS model to grow all current inventory plots for 1 year. All growth and mortality estimates were based on growth and mortality through December 31, 1992, in the Eastern Upper Peninsula of Michigan.

6. Average annual removals estimates

Average annual growing-stock and sawtimber removals (1980 to 1992) were estimated only from the remeasured plots; new plots were not used to estimate removals. These estimates are obtained from trees measured in the last survey and cut or otherwise removed from the timberland base. All removal estimates were based on removals through December 31, 1992, in the Eastern Upper Peninsula of Michigan. Because remeasurement plots make up about one-half of the total ground plots, average annual removals estimates have greater sampling errors than volume and growth estimates.

Tree and Log Grades

On approximately one-third of the sample plots in Michigan's Eastern Upper Peninsula, all sawtimber sample trees were graded for quality and assigned either a tree grade (hardwoods) or a log grade (softwoods). Tree and log

grades were based on the evaluation of external characteristics as indicators of quality. The volume yield by grade for this sample was used to distribute the volume of the ungraded sample trees by species group. Hardwood sawtimber trees were graded according to "Hardwood tree grades for factory lumber" (Hanks 1976). The best 12-foot section of the lowest 16-foot hardwood log was used for grading. Hardwood sawtimber trees that did not meet minimum tree grade specifications for grades 1 through 3 were assigned grade 4

according to Forest Service standard specifications for hardwood construction logs described in "A guide to hardwood log grading" (Rast *et al.* 1973). Red pine and jack pine sawtimber trees were graded based on specifications described in "Forest Service log grades for southern pines" (Campbell 1964). White pine and other softwood sawtimber trees were graded according to specifications described in the circular "Log grades" (Peterson 1965). For all softwoods, the first merchantable 16-foot log, or shorter lengths down to 12 feet, was used for grading.

Hardwood Tree Grades for Factory Lumber

Grade factor	Tree grade 1	Tree grade 2	Tree grade 3
Length of grading zone (feet)	Butt 16	Butt 16	Butt 16
Length of grading section ^a (feet)	Best 12	Best 12	Best 12
D.b.h., minimum (inches)	16 ^b	13	11
Diameter, minimum inside bark at top of grading section (inches)	13 ^b 16 20	11 ^c 12	8
Clear cuttings (on the three best faces) ^d			
Length, minimum (feet)	7 5 3	3 3	2
Number on face (maximum)	2	2 3	e
Yield in face length (minimum)	5/6	4/6	3/6
Cull deduction (including crook and sweep, but excluding shake) maximum within grading section (percent)	9	g ^f	50

^a Whenever a 14- or 16-foot section of the butt 16-foot log is better than the best 12-foot section, the grade of the longer section will become the grade of the tree. This longer section, when used, is the basis for determining the grading factors.

^b In basswood and ash, diameter inside bark (d.i.b.) at top of grading section must be 12 inches and d.b.h. must be 15 inches.

^c Grade 2 trees can be 10 inches d.i.b. at top of grading section if otherwise meeting surface requirements for small grade 1's.

^d A clear cutting is a portion of a face free of defects, extending the width of the face. A face is one-fourth of the surface of the grading section as divided lengthwise.

^e Unlimited.

^f Fifteen percent crook and sweep or 40 percent total cull deduction are permitted in grade 2, if size and surface of grading section qualify as grade 1. If rot shortens the required clear cuttings to the extent of dropping the butt log to grade 2, do not drop the tree's grade to 3 unless the cull deduction for rot is greater than 40 percent.

**Forest Service Standard Specifications for Hardwood Construction Logs
(tie and timber logs) ^a**

Position in tree	Butts and uppers
Min. diameter, small end	8 inches +
Min. length without trim	8 feet +
Clear cuttings	No requirements
Sweep allowance	One-fourth small end d.i.b. for each 8 feet of length. One-half dib for logs 16 feet long.
Sound surface defects:	
Single knots	Any number, if no knot has an average diameter above the callus in excess of one-third of the log diameter at point of occurrence.
Whorled knots	Any number, if the sum of knot diameters above the callus does not exceed one-third of the log diameter at point of occurrence.
Holes	Any number not exceeding knot specifications as long as they do not extend over 3 inches into contained tie or timber.
Unsound defects :	
Surface	Same requirements as for sound defects if they extend into included timber. No limit if they do not.
Interior	None permitted except one shake not more than one-third the width of contained tie or timber, and one split, not over 5 inches.

^a *These specifications are minimum for the class. If, from a group of logs, factory logs are selected first, thus leaving only nonfactory logs from which to select construction logs, then the quality range of the construction logs so selected is limited, and the class may be considered a grade. If selection for construction logs is given first priority, it may be necessary to subdivide the class into grades.*

Log Grades for Jack Pine and Red Pine

- Grade 1:** Logs with three or four clear faces on the 16-foot grading section. ^a
Grade 2: Logs with one or two clear faces on the 16-foot grading section.
Grade 3: Logs with no clear faces on the 16-foot grading section.

After the tentative grade is established from above, the log will be reduced one grade for each of the following defects, except that no log can be reduced below grade 3. Net scale after deduction for defect must be at least 50 percent of the gross contents of the log.

- Sweep.** Degrade any tentative grade 1 or 2 log one grade if sweep amounts to 3 or more inches and equals or exceeds one-third of the diameter inside bark at the small end.
- Heart rot.** Degrade any tentative grade 1 or 2 log one grade if conk, punk knots, massed hyphae, or other evidence of advanced heart rot is found anywhere on the log.

^a *A face is one-fourth of the circumference in width extending full length of the log. Clear faces are those free of: knots measuring more than 1/2-inch in diameter, overgrown knots of any size, and holes more than 1/4-inch in diameter. Faces may be rotated to obtain the maximum number of clear ones.*

Eastern White Pine Sawlog Grade Specifications

Grading factor	Log grade 1	Log grade 2	Log grade 3	Log grade 4
1. Minimum scaling diameter (inches)	14 ^a	6	6	6
2. Minimum log length (feet)	10 ^b	8	8	8
3. Maximum weevil injury (number)	None	None	2 injuries ^c	No limit
4. Minimum face requirements	Two full length or four 50% ^d length good faces (in addition, log knots on balance of faces shall not exceed size limit of grade 2 logs	NO GOOD FACES REQUIRED Maximum diameter of log knots on three best faces: SOUND RED KNOTS not to exceed 1/6 scaling diameter and 3" maximum OVERGROWN/DEAD/BLACK KNOTS not to exceed 1/12 scaling diameter and 1 1/2" max.		Includes all logs not qualifying for No. 3 or better and have at least 1/3 of their gross volume in sound wood suitable for manufacture into standard lumber
5. Maximum sweep or crook (%)	20	30	40	66 2/3
6. Maximum total scaling deduction (%)	50	50	50	66 2/3

AFTER THE TENTATIVE LOG GRADE IS ESTABLISHED FROM FACE EXAMINATION, THE LOG WILL BE REDUCED IN GRADE WHENEVER THE FOLLOWING DEFECTS ARE EVIDENT

7. Conks, punk knots, and pine borer damage on bark surface ^e.
Degrade one grade if present on one face.
Degrade two grades if present on two faces.
Degrade three grades if present on three or more faces.
 8. Log end defects: red rot, ring shake, heavy stain and pine borer damage outside the heart center of log^e. Consider log as having a total of 8 quarters (4 on each end) and degrade as indicated.
Degrade one grade if present in 2 quarters of log ends.
Degrade two grades if present in 3 or 4 quarters of log ends.
Degrade three grades if present in 5 or more quarters of log ends.
- a. 12 and 13 inch logs with four full-length good faces are acceptable.
 - b. 8 foot logs with four full-length good faces are acceptable.
 - c. 8 foot Number 3 logs limited to one weevil injury.
 - d. Minimum 50% length good face must be at least 6 feet.
 - e. Factors 7 and 8 are not cumulative (total degrade based on more serious of the two). No log to be degraded below grade 4 if net scale is at least one third of gross scale.

Log Grades for All Other Softwood Logs

Grade 1

1. Trees must be 16 inches dib or larger, 10 feet in length or longer, and with deduction for defect, not over 30 percent of gross scale.
2. Logs must be at least 75 percent clear on each of three faces.
3. All knots outside clear cutting must be sound and not more than 2-1/2 inches in size.

Grade 2

1. Logs must be 12 inches dib or larger, 10 feet in length or longer, and with a net scale after deduction for defect of at least 50 percent of the gross contents of the log.
2. Logs must be at least 50 percent clear on each of three faces or 75 percent clear on two faces.

Grade 3

1. Logs must be 6 inches dib or larger, 8 feet in length or longer, and with a net scale after deduction for defect of at least 50 percent of the gross contents of the log.

Note: Diameters are d.i.b. at small end of grading section, and percent clear refers to percent clear in one continuous section.

METRIC EQUIVALENTS OF UNITS USED IN THIS REPORT

- 1 acre = 4,046.86 square meters or 0.405 hectare.
 1,000 acres = 405 hectares.
 1 cubic foot = 0.0283 cubic meter.
 1 foot = 30.48 centimeters or 0.3048 meter.
 1 inch = 25.4 millimeters, 2.54 centimeters, or 0.0254 meter.
 1 pound = 0.454 kilogram.
 1 ton = 0.907 metric ton.

TREE SPECIES GROUPS IN MICHIGAN'S EASTERN UPPER PENINSULA

Species names are based on Little, 1981.

SOFTWOODS

- Balsam fir *Abies balsamea*
 Tamarack *Larix laricina*
 White spruce *Picea glauca*
 Black spruce *Picea mariana*
 Jack pine *Pinus banksiana*
 Red pine *Pinus resinosa*
 Eastern white pine *Pinus strobus*
 Northern white-cedar *Thuja occidentalis*
 Eastern hemlock *Tsuga canadensis*
 Other softwoods:
 Engelmann spruce *Picea engelmannii*
 Eastern redcedar *Juniperus virginiana*
 Scotch pine *Pinus sylvestris*

HARDWOODS

- Hard maple¹
 Sugar maple *Acer saccharum*
 Soft maple²

- Red maple *Acer rubrum*
 Silver maple *Acer saccharinum*
 Birch
 Yellow birch¹ *Betula alleghaniensis*
 River birch² *Betula nigra*
 Paper birch² *Betula papyrifera*
 Bitternut hickory¹ *Carya cordiformis*
 Hackberry *Celtis occidentalis*
 Persimmon *Diospyros virginiana*
 American beech *Fagus grandifolia*
 Ash
 White ash¹ *Fraxinus americana*
 Black ash² *Fraxinus nigra*
 Green ash¹ *Fraxinus pennsylvanica*
 Butternut² *Juglans cinerea*
 Black walnut¹ *Juglans nigra*
 White poplar *Populus alba*
 Balsam poplar *Populus balsamifera*
 Cottonwood *Populus deltoides*
 Bigtooth aspen² *Populus grandidentata*
 Quaking aspen² *Populus tremuloides*
 Black cherry *Prunus serotina*
 White oak¹
 White oak *Quercus alba*
 Swamp white oak *Quercus bicolor*
 Bur oak *Quercus macrocarpa*
 Red oak¹
 Northern pin oak *Quercus ellipsoidalis*
 Pin oak *Quercus palustris*
 Northern red oak *Quercus rubra*

¹This species or species group is considered a hard hardwood, with an average specific gravity greater than or equal to 0.50.

²This species or species group is considered a soft hardwood, with an average specific gravity of less than 0.50.

American basswood	<i>Tilia americana</i>
Elm	
Winged elm ²	<i>Ulmus alata</i>
American elm ²	<i>Ulmus americana</i>
Slippery elm ²	<i>Ulmus rubra</i>
Rock elm ¹	<i>Ulmus thomasii</i>
Other hardwoods	
Boxelder	<i>Acer negundo</i>
Ohio Buckeye	<i>Aesculus glabra</i>
Sweet birch ¹	<i>Betula lenta</i>
Northern catalpa	<i>Catalpa speciosa</i>
Noncommercial species	
Striped maple	<i>Acer pennsylvanicum</i>
Mountain maple	<i>Acer spicatum</i>
American hornbeam	<i>Carpinus caroliniana</i>
Hawthorn	<i>Crataegus</i> spp.
Apple	<i>Malus</i> spp.
Eastern hophornbeam	<i>Ostrya virginiana</i>
Canada plum	<i>Prunus nigra</i>
Pin cherry	<i>Prunus pensylvanica</i>
Wild plum	<i>Prunus</i> spp.
Chokecherry	<i>Prunus virginiana</i>
Peachleaf willow	<i>Salix amygdaloides</i>
Black willow	<i>Salix nigra</i>
Willow spp.	<i>Salix</i> spp.

DEFINITION OF TERMS

Average annual removals from growing stock.

—The average net growing-stock volume in growing-stock trees removed annually for forest products (including roundwood products and logging residues) and for other uses (see Other removals). Average annual removals of growing stock are reported for a period of several years (1980 to 1993 in this report) and are based on information obtained from remeasurement plots (see Survey Procedures in Appendix).

Average annual removals from sawtimber.—

The average net board foot sawtimber volume of live sawtimber trees removed annually for forest products (including roundwood products and other uses [see Other removals]). Average annual removals of sawtimber are reported for a period of several years (1980 to 1993 in this report) and are based on information obtained from remeasurement plots (see Survey Procedures in Appendix).

Average net annual growth of growing stock.

—The annual change in volume of sound wood in live sawtimber and

poletimber trees and the total volume of trees entering these classes through in-growth, less volume losses resulting from natural causes.

Average net annual growth of sawtimber.—

The annual change in the volume of live sawtimber trees and the total volume of trees reaching sawtimber size, less volume losses resulting from natural causes.

Basal area.—Tree area in square feet of the cross section at breast height of a single tree. When the basal areas of all trees in a stand are summed, the result is usually expressed as square feet of basal area per acre.

Butt log.—The first 12 to 16 feet from a 1-foot stump that could be, or is, cut. Minimum standards for butt logs vary by species.

Clear panel.—A section of hardwood tree surface one-fourth the circumference of the tree and at least 2 feet long, free of limbs, knots, bumps, and other indications of defect that preclude clear cuttings.

Commercial species.—Tree species presently or prospectively suitable for industrial wood products. (Note: Excludes species of typically small size, poor form, or inferior quality such as hophornbeam, osage-orange, and redbud.)

County and municipal land.—Land owned by counties and local public agencies or municipalities, or land leased to these governmental units for 50 years or more.

Cropland.—Land under cultivation within the past 24 months; including cropland harvested, crop failures, cultivated summer fallow, idle cropland used only for pasture, orchards, and land in soil improvement crops, but excluding land cultivated in developing improved pasture.

Cull.—Portions of a tree that are unusable for industrial wood products because of rot, missing or dead material, or other defect.

Diameter class.—A classification of trees based on diameter outside bark, measured at breast height (d.b.h.). Two-inch diameter classes are commonly used in Forest Inventory and Analysis, with the even inch the

approximate midpoint for a class. For example, the 6-inch class includes trees 5.0 through 6.9 inches d.b.h.

Diameter at breast height (d.b.h.).—The outside bark diameter at 4.5 feet (1.37 m) above the forest floor on the uphill side of the tree. For determining breast height, the forest floor includes the duff layer that may be present, but does not include unincorporated woody debris that may rise above the ground line.

Face.—A section of the tree surface one-fourth the circumference of the tree extending the full length of the log.

Farm.—Either a place operated as a unit of 10 acres or more from which the sale of agricultural products totals \$50.00 or more annually, or a place operated as a unit of less than 10 acres from which the sale of agricultural products for a year amounts to at least \$250.00. Places having less than the \$50.00 or \$250.00 minimum estimated sales in a given year are also counted as farms if they can normally be expected to produce products in sufficient quantity to meet the requirements of the definition.

Farmer-owned land.—Land owned by farm operators whether part of the farmstead or not. (Note: Excludes land leased by farm operators from nonfarm owners, such as railroad companies and States.)

Forest industry land.—Land owned by companies or individuals operating wood-using plants.

Forest land.—Land at least 16.7 percent stocked by forest trees of any size, or formerly having had such tree cover, and not currently developed for nonforest use. (Note: Stocking is measured by comparing specified standards with basal area and/or number of trees, age or size, and spacing.) The minimum area for classification of forest land is 1 acre. Roadside, streamside, and shelterbelt strips of timber must have a crown width of at least 120 feet to qualify as forest land. Unimproved roads and trails, streams, or other bodies of water or clearings in forest areas shall be classed as forest if less than 120 feet wide. (See definitions for Land, Timberland, Reserved forest land, Other forest land, Stocking, and Water.)

Forest type.—A classification of forest land based on the species forming a plurality of live tree stocking. Major forest types in the State are:

Jack pine.—Forests in which jack pine comprises a plurality of the stocking. (Common associates include eastern white pine, red pine, aspen, birch, and maple.)

Red pine.—Forests in which red pine comprises a plurality of the stocking. (Common associates include eastern white pine, jack pine, aspen, birch, and maple.)

Eastern white pine.—Forests in which eastern white pine comprises a plurality of the stocking. (Common associates include red pine, jack pine, aspen, birch, and maple.)

Balsam fir.—Forests in which balsam fir and white spruce comprise a plurality of stocking with balsam fir the most common. (Common associates include white spruce, aspen, maple, birch, northern white-cedar, and tamarack.)

White spruce.—Forests in which white spruce and balsam fir comprise a plurality of the stocking with white spruce the most common. (Common associates include balsam fir, aspen, maple, birch, northern white-cedar, and tamarack.)

Black spruce.—Forests in which swamp conifers comprise a plurality of the stocking with black spruce the most common. (Common associates include tamarack and northern white-cedar.)

Northern white-cedar.—Forests in which swamp conifer species comprise a plurality of the stocking with northern white-cedar the most common. (Common associates include tamarack and black spruce.)

Tamarack.—Forests in which swamp conifers comprise a plurality of the stocking with tamarack the most common. (Common associates include black spruce and northern white-cedar.)

Oak-hickory.—Forests in which northern red oak, white oak, bur oak, or hickories, singly or in combination, comprise a plurality of the stocking. (Common associates include jack pine, beech, yellow-poplar, elm, and maple.)

Elm-ash-soft maple.—Forests in which lowland elm, ash, red maple, silver maple, and cottonwood, singly or in combination, comprise a plurality of the stocking. (Common associates include birch, spruce, and balsam fir.)

Maple-birch.—Forests in which sugar maple, basswood, yellow birch, upland American elm, and red maple, singly or in combination, comprise a plurality of the stocking. (Common associates include birch, spruce, and balsam fir.)

Aspen.—Forests in which quaking aspen or bigtooth aspen, singly or in combination, comprise a plurality of the stocking. (Common associates include balsam poplar, balsam fir, and paper birch.)

Paper birch.—Forests in which paper birch comprises a plurality of the stocking. (Common associates include maple, aspen, and balsam fir.)

Balsam poplar.—Forests in which balsam poplar comprises a plurality of the stocking. (Common associates include aspen, elm, and ash.)

Growing-stock tree.—A live tree of commercial species that meets specified standards of size, quality, and merchantability. (Note: Excludes rough, rotten, and dead trees.)

Growing-stock volume.—Net volume in cubic feet of growing-stock trees 5.0 inches d.b.h. and over, from 1 foot above the ground to a minimum 4.0 inch top diameter (outside bark) of the central stem or to the point where the central stem breaks into limbs.

Hard hardwoods.—Hardwood species with an average specific gravity greater than 0.50 such as oaks, hard maple, and hickories.

Hardwoods.—Dicotyledonous trees, usually broad-leaved and deciduous. (See Soft hardwoods and Hard hardwoods.)

Improved pasture.—Land currently improved for grazing by cultivation, seeding, irrigation, or clearing of trees and brush.

Indian owned land.—Land held in trust by the United States for tribes or individual Native Americans.

Industrial wood.—All roundwood products except residential fuelwood.

Land.—A. *Bureau of the Census.* Dry land and land temporarily or partly covered by water such as marshes, swamps, and river flood plains (omitting tidal flats below mean high tide); streams, sloughs, estuaries, and canals less than one-eighth of a statute mile

wide; and lakes, reservoirs, and ponds less than 40 acres in area.

B. *Forest Inventory and Analysis.* The same as the Bureau of the Census, except minimum width of streams, etc., is 120 feet and minimum size of lakes, etc., is less than 1 acre.

Live trees.—Growing-stock, rough, and rotten trees 1.0 inch d.b.h. and larger.

Log grade.—A log classification based on external characteristics as indicators of quality or value. (See Appendix for specific grading factors used.)

Marsh.—Nonforest land that characteristically supports low, generally herbaceous or shrubby vegetation and that is intermittently covered with water.

Merchantable.—Refers to a pulpwood or saw-log section that meets pulpwood or saw-log specifications, respectively.

Miscellaneous Federal land.—Federal land other than National Forest and land administered by the Bureau of Land Management or Bureau of Indian Affairs.

Miscellaneous private land.—Privately owned land other than forest-industry and farmer-owned land.

Mortality.—The volume of sound wood in growing-stock and sawtimber trees that die annually.

National Forest land.—Federal land that has been legally designated as National Forest or purchase units, and other land administered by the USDA Forest Service.

Net volume.—Gross volume less deductions for rot, sweep, or other defect affecting use for timber products.

Noncommercial species.—Tree species of typically small size, poor form, or inferior quality that normally do not develop into trees suitable for industrial wood products.

Nonforest land.—Land that has never supported forests, and land formerly forested where use for timber management is precluded by development for other uses. (Note: Includes areas used for crops, improved

pasture, residential areas, city parks, improved roads of any width and adjoining clearings, powerline clearings of any width, and 1- to 40-acre areas of water classified by the Bureau of the Census as land. If intermingled in forest areas, unimproved roads and nonforest strips must be more than 120 feet wide and more than 1 acre in area to qualify as nonforest land.)

a. *Nonforest land without trees.*—Nonforest land with no live trees present.

b. *Nonforest land with trees.*—Nonforest land with one or more trees per acre at least 5 inches d.b.h.

Nonstocked land.—Forest land less than 16.7 percent stocked with all live trees.

Other forest land.—Forest land not capable of producing 20 cubic feet per acre per year of industrial wood crops under natural conditions and not associated with urban or rural development. These sites often contain tree species that are not currently utilized for industrial wood production or trees of poor form, small size, or inferior quality that are unfit for industrial products. Unproductivity may be the result of adverse site conditions such as sterile soil, dry climate, poor drainage, high elevation, and rockiness. This land is not withdrawn from timber utilization.

Other removals.—Growing-stock trees removed but not utilized for products, or trees left standing but “removed” from the timberland classification by land use change. Examples are removals from cultural operations such as timber stand improvement work, land clearing, and changes in land use.

Ownership size class.—The amount of timberland owned by one owner, regardless of the number of parcels.

Pasture.—Land presently used for grazing or under cultivation to develop grazing.

Poletimber stand.—(See Stand-size class.)

Poletimber tree.—A tree of commercial species at least 5.0 inches d.b.h. but smaller than sawtimber size.

Potential productivity class.—A classification of forest lands in terms of inherent capacity to grow crops of industrial wood. The class identifies the potential growth in merchantable cubic feet/acre/year at culmination of mean annual increment of fully stocked natural stands.

Reserved forest land.—Forest land withdrawn from timber utilization through statute, administrative regulation, designation, or exclusive use for Christmas tree production, as indicated by annual shearing.

Rotten tree.—A tree that does not meet regional merchantability standards because of excessive unsound cull. May include noncommercial tree species.

Rough tree.—A tree that does not meet regional merchantability standards because of excessive sound cull. May include noncommercial tree species.

Roundwood products.—Logs, bolts or other round sections (including chips from roundwood) cut from trees for industrial or consumer uses. (Note: Includes saw logs, veneer logs and bolts; cooperage logs and bolts; pulpwood; fuelwood; pilings; poles; posts; hewn ties; mine timbers; and various other round, split, or hewn products.)

Salvable dead tree.—A standing or down dead tree considered merchantable by regional standards.

Sapling.—A live tree 1.0 to 5.0 inches d.b.h.

Sapling-seedling stand.—(See Stand-size class.)

Saw log.—A log meeting minimum standards of diameter, length, and defect. A saw log must be at least 8 feet long, sound, straight, have a minimum diameter outside bark (d.o.b.) of 7.0 inches for softwoods and 9.0 inches for hardwoods, or have other combinations of size and defect specified by regional standards.

Saw-log portion.—That part of the bole of sawtimber trees between the stump and the saw-log top.

Saw-log top.—The point on the bole of sawtimber trees above which a saw log cannot be produced. The minimum saw-log top is 7.0 inches d.o.b. for softwoods and 9.0 inches d.o.b. for hardwoods.

Sawtimber stand.—(See Stand-size class.)

Sawtimber tree.—A tree of commercial species containing at least a 12-foot saw log or two noncontiguous saw logs 8 feet or longer, and meeting regional specifications for freedom from defect. Softwoods must be at least 9.0 inches d.b.h. Hardwoods must be at least 11.0 inches d.b.h.

Sawtimber volume.—Net volume of the sawlog portion of live sawtimber in board feet, International 1/4-inch rule (unless specified otherwise), from the stump to a minimum 7 inches top d.o.b. for softwoods and a minimum 9 inches top d.o.b. for hardwoods.

Seedling.—A live tree less than 1.0 inch d.b.h. that is expected to survive. Only softwood seedlings more than 6 inches tall and hardwood seedlings more than 1 foot tall are counted.

Short-log (rough tree).—Sawtimber-size trees of commercial species that contain at least one merchantable 8- to 11-foot saw log but not a 12-foot saw log.

Site index.—An expression of forest site quality based on the height of a free-growing dominant, or codominant tree of a representative species in the forest type at age 50.

Soft hardwoods.—Hardwood species with an average specific gravity less than 0.50 such as gum, yellow-poplar, cottonwood, red maple, basswood, and willow.

Softwoods.—Coniferous trees, usually evergreen, having needles or scale-like leaves.

Stand.—A group of trees on a minimum of 1 acre of forest land that is stocked by forest trees of any size.

Stand-age class.—Age of main stand. Main stand refers to trees of the dominant forest type and stand-size class.

Stand-size class.—A classification of stocked (see Stocking) forest land based on the size class of live trees on the area; that is, sawtimber, poletimber, or seedlings and saplings.

a. Sawtimber stands.—Stands with half or more of live stocking in sawtimber or poletimber trees, and with sawtimber stocking at least equal to poletimber stocking.

b. Poletimber stands.—Stands with half or more live stocking in poletimber and/or sawtimber trees, and with poletimber stocking exceeding that of sawtimber.

c. Sapling-seedling stands.—Stands with more than half of the live stocking in saplings and/or seedlings.

State land.—Land owned by States, or leased to them for 50 years or more.

Stocking.—The degree of occupancy of land by live trees, measured by basal area; and/or the number of trees in a stand by size or age and spacing, compared to the basal area; and/or number of trees required to fully utilize the growth potential of the land; that is, the stocking standard.

A stocking percent of 100 indicates full utilization of the site and is equivalent to 80 square feet of basal area per acre in trees 5.0 inches d.b.h. and larger. In a stand of trees less than 5 inches d.b.h., a stocking percent of 100 would indicate that the present number of trees is sufficient to produce 80 square feet of basal area per acre when the trees reach 5 inches d.b.h.

Stands are grouped into the following stocking classes:

Overstocked stands.—Stands in which stocking of live trees is 133 percent or more.

Fully stocked stands.—Stands in which stocking of live trees is from 100.0 to 132.9 percent.

Medium stocked stands.—Stands in which stocking of live trees is from 60.0 to 99.9 percent.

Poorly stocked stands.—Stands in which stocking of live trees is from 16.7 to 59.9 percent.

Nonstocked areas.—Timberland on which stocking of live trees is less than 16.7 percent.

Timberland.—Forest land that is producing, or capable of producing, in excess of 20 cubic feet per acre per year of industrial wood crops under natural conditions. In addition, the forest land must not be withdrawn from timber utilization, and not associated with urban or rural development. Currently inaccessible and inoperable areas are included.

Tree.—A woody plant usually having one or more perennial stems, a more or less definitely formed crown of foliage, and a height of at least 12 feet at maturity.

Tree grade.—A tree classification based on external characteristics as indicators of quality or value, used for hardwood species. (See Appendix for specific grading factors used.)

Tree size class.—A classification of trees based on diameter at breast height, including sawtimber trees, poletimber trees, saplings, and seedlings.

Unproductive forest land.—Forest land incapable of producing 20 cubic feet per acre per year of industrial wood under natural conditions because of adverse site conditions. (Note: Adverse conditions include sterile soils, dry climate, poor drainage, high elevation, steepness, and rockiness.)

Upper stem portion.—That part of the bole of sawtimber trees above the saw-log top to a minimum top diameter of 4.0 inches outside bark, or to the point where the central stem breaks into limbs.

Water.—(a) *Bureau of the Census.*—Permanent inland water surfaces, such as lakes, reservoirs, and ponds at least 40 acres in area; and streams, sloughs, estuaries, and canals at least one-eighth of a statute mile wide.

(b) *Noncensus.*—Permanent inland water surfaces, such as lakes, reservoirs, and ponds from 1 to 39.9 acres in area; and streams, sloughs, estuaries, and canals from 120 feet to one-eighth of a statute mile wide.

Wooded pasture.—Improved pasture with more than 16.7 percent stocking in live trees but less than 25 percent stocking in growing-stock trees. Area is currently improved for grazing or there is evidence of grazing.

¹ An estimate of current gross growth may be computed by adding current mortality to current net growth.

² Based on mill survey data (Hackett and Pilon 1993). For the Eastern Upper Peninsula, 1990 is the most current mill survey.

³ International 1/4 inch rule.

* Removals for the black spruce species group are included in the removals for white spruce.

** Removals for the white and green ash species group are included in the removals for black ash.

*** Removals for the bigtooth aspen species group are included in the removals for quaking aspen.

Our job at the North Central Forest Experiment Station is discovering and creating new knowledge and technology in the field of natural resources and conveying this information to the people who can use it. As a new generation of forests emerges in our region, managers are confronted with two unique challenges: (1) Dealing with the great diversity in composition, quality, and ownership of the forests, and (2) Reconciling the conflicting demands of the people who use them. Helping the forest manager meet these challenges while protecting the environment is what research at North Central is all about.
