ILLINOIS' TIMBER RESOURCES

FOREWORD

This is a report on the second comprehensive inventory of Illinois' forest resource. The first inventory, made in 1947 and 1948, was reported by D. B. King and R. K. Winters of the Central States Forest Experiment Station under the title "Forest Resources and Industries of Illinois," and published as Bulletin 562 of the University of Illinois Agricultural Experiment Station. Both surveys were a part of the nationwide Forest Survey program authorized by the McSweeney-McNary Forest Research Act of 1928. The field work of the second survey began in September 1961 and was completed in November 1962.

Since the first survey, changes in land use, timber cut, growth, and mortality have modified the forests (type map on inside of back cover). This report weighs these changes and points out trends that may affect future supplies for local wood-using industries. Some of the data have been presented previously in Research Notes of the Central States Forest Experiment Station (see outside back cover).

The survey was made by the Lake States Forest Experiment Station, St. Paul, Minn., and the Central States Forest Experiment Station, Columbus, Ohio. The Illinois Department of Conservation and the University of Illinois assisted in collecting timber cut and product data. The North Central Region of the U.S. Forest Service collected data for the Shawnee National Forest, and the Agricultural Stabilization and Conservation Service provided the aerial photos used.

Clarence D. Chase, leader of the Forest Survey Project at St. Paul, directed the survey. He was assisted by Paul DeBald, field supervisor, and his crew of Richard Groff, Eugene Carpenter, Harry Nickless, Melvin Goldie, David Benson, Donald Rardin, and John Rice. Arthur Horn of the Lake States Station compiled the timber cut and product data, and Burton Essex the forest inventory and growth data.

[1] Burton L. Essex, Resource Analyst at the Lake States Forest Experiment Station, is a specialist in timber inventory computing and analysis. His recent work has included the Forest Surveys in Kentucky, Kansas, and South Dakota as well as Illinois. David A. Gansner, Resource Analyst at the Central States Forest Experiment Station, has coordinated Forest Survey work in the Central States since 1961. His recent publications include the major report on the survey in Missouri and unit reports for Kentucky.

[2] The Lake States Forest Experiment Station is located at St. Paul, Minn., and maintained in cooperation with the University of Minnesota.

CONTENTS

THE TIMBER RESOURCE IN BRIEF

The forests of Illinois seem to have changed little since the Forest Survey of 1948. According to the 1962 Survey, they still occupy 11 percent of the total land area, and timber volume is nearly as much as in 1948. However, many important changes actually have taken place, and they will have a measurable effect on the forests and the wood-using industries that they support.

The volume per acre of sound wood is greater today than it has been in many years. However, about 80 percent of the present growth is taking place in trees less than 11 inches in diameter.

Industries such as veneer and cooperage that depend primarily on larger trees will find it more and more difficult to obtain the high-quality logs they need. Sawtimber volume has decreased 16 percent since the last survey because growth has not been sufficient to replace the sawtimber removed in harvesting, land clearing, and death from natural causes. Net growth has been reduced nearly as much by high mortality as by heavy cutting. Recent mortality caused by diseases such as Dutch elm and oak wilt is nearly as great as the mortality from all causes recorded at the time of the previous survey. Most of the volume lost was large sawtimber. Volume in trees 19 inches and larger declined an average of 108 million board feet per year between 1948 and 1962. As a result, the yield of high-grade material is lower now than several years ago. However, there has been no decline in potential quality. In fact, the volume in good-quality, young sawtimber trees is increasing and, if these trees are allowed to grow into larger diameter classes, the volume of grade F1 and F2 logs will increase.

Just as serious as the loss of sawtimber volume in the larger trees is the declining productivity of older stands. These stands have been cut over several times to remove better-quality trees. The remaining trees are defective and rough, with a large proportion of low-grade wood that adds little value to the forest resource. Slow-growing, low-quality trees are occupying space that could better be used by young, thrifty saplings. The wood that could be cut from these deteriorating stands, plus the wood from thinnings and improvement cuttings in younger stands, would amount to 112 million cubic feet annually. This desirable cut is nearly four times the present timber harvest.

Although the amount of wood harvested from Illinois' forests in 1961 is less than that of 1947, the production of nearly all major commodities is up. Lumber sawn by local mills has increased, and 1961 production was 22 percent higher than in 1947. Veneer and cooperage log production has risen also, but not nearly as fast as the harvest of pulpwood. The cut of pulpwood has more than doubled since the last survey. If this trend continues as expected, pulpwood will soon become second only to lumber in total volume of product. The overall decline in timber products output is primarily the result of declining fuelwood use. Today's fuelwood production is a little less than half of what it was in 1947.

PRESENT TIMBER SUPPLY

Timber Volumes Decreasing

Because Illinois land is relatively flat and fertile, most of it is in agriculture. Forests occupy only 11 percent of the total land area (fig. 1). These forests support a growing-stock volume of 2,344 million cubic feet—3 percent less than in 1948. Most of this decline can be attributed to a moderate drop of 180,000 acres in the area of commercial forest land. Although average volume per acre increased between surveys, it was not enough to offset this acreage loss.

Poletimber trees make up 34 percent of the forests' total live tree volume (fig. 2). Their volume has increased from 798 to 821 million cubic feet. Sawtimber trees still make up 63 percent of the total live tree volume, but their numbers have been decreasing. Because cutting has been concentrated in the larger trees, Illinois forest stands average a little younger now than they did in 1948.

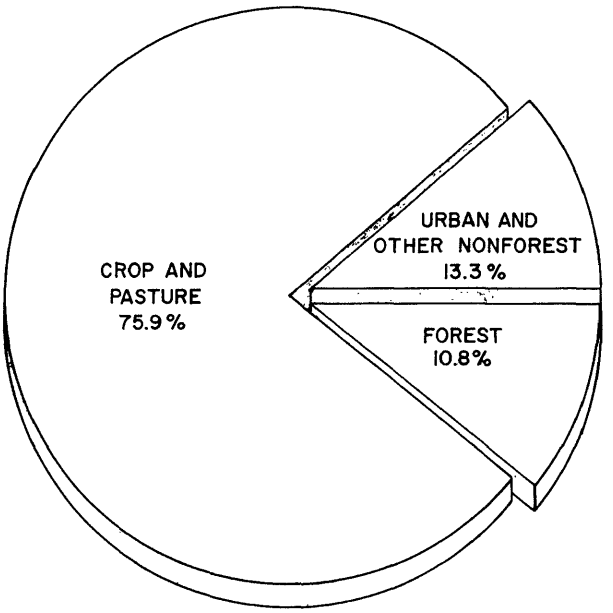

Figure 1.—Distribution of land area by use classes, 1962.

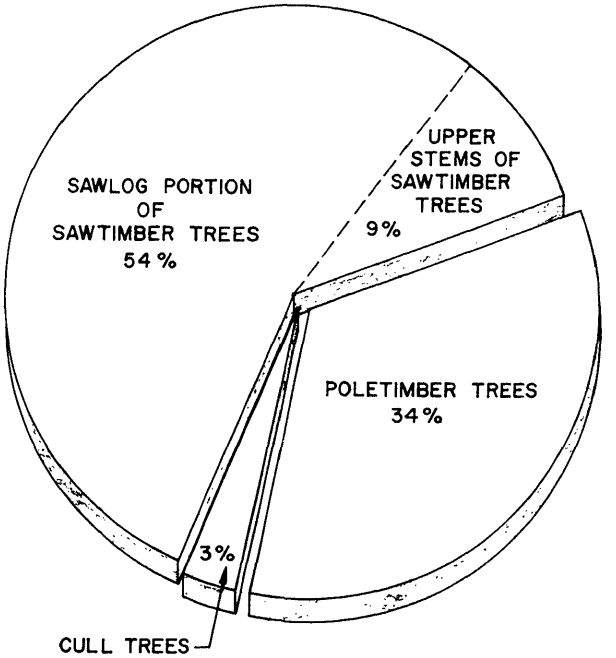

Figure 2.—Proportion of live timber on commercial forest land by kinds of material, 1962.

Nearly 70 percent of the State's growing-stock volume is in the Claypan and Southern Survey Units —roughly the southern third of the State (fig. 3). The combined wood volume of these two units amounted to 1,616 million cubic feet in 1962, an increase of nearly 9 percent. The increase was due in part to a slight enlargement in the area of commercial forest land. More important, however, was the increasing volume in existing stands brought on by accumulating timber growth. In the two southern units average volume per acre increased from 619 to 659 cubic feet. The following tabulation shows the change in growing stock volume by survey unit.

Survey Unit	Million cubic feet in— 1948	1962	Change (percent)
Prairie	931.0	728.0	−22
Claypan	812.4	929.0	+14
Southern	671.8	687.2	+ 2
Total	2,415.2	2,344.2	− 3

Illinois forests are predominantly hardwood. Nearly 42 percent of the total growing-stock volume in the State is in the white and red oaks. However, the composition is changing. Volume of the white oak group dropped 139 million cubic feet between surveys, and red oak declined 68 million cubic feet (fig. 4). Through the years the oaks have been the species most sought by local forest industries. In 1961, they made up almost 46 percent of the total growing-stock harvest. Coming in rapidly to fill the void left by the oaks is a group of species labeled "other hardwoods."

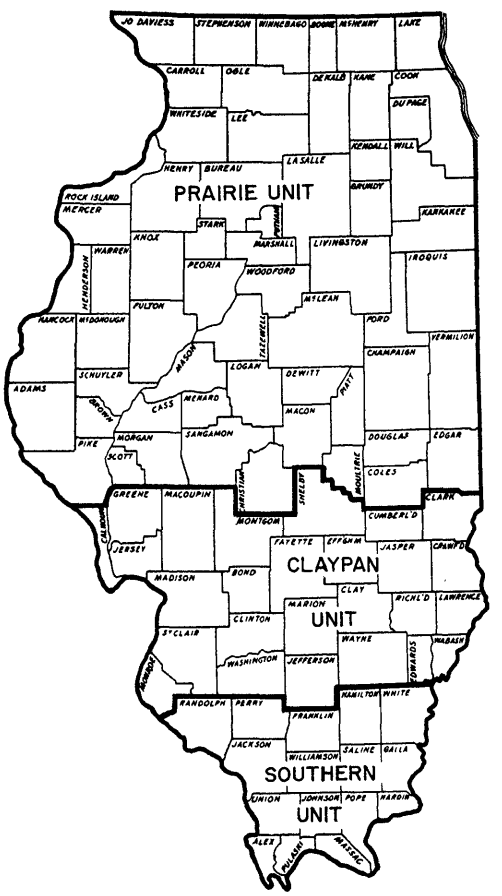

Figure 3.—Forest Survey units in Illinois.

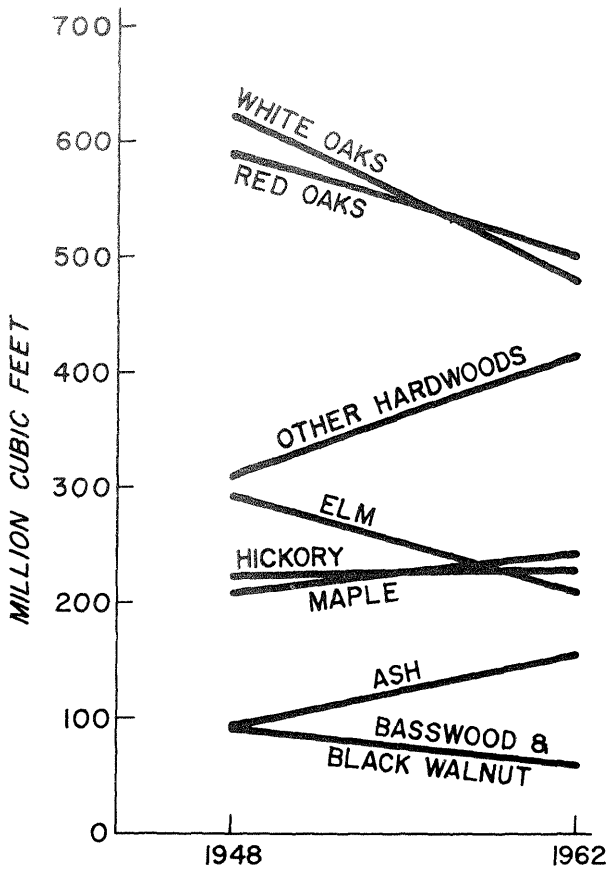

Figure 4.—Change in growing-stock volume by major species groups, 1948-1962.

This group, comprised of yellow-poplar, cottonwood, sycamore, sweetgum, and many other species, has increased in growing-stock volume by about one-third.

In contrast to the relatively stable growing-stock volume is a sharp decline in sawtimber volume. Even though the area of sawtimber stands increased, the volume of sawtimber has dropped 16 percent to the current 8,576 million board feet. In 1948, the average volume per acre of sawtimber trees was 2,600 board feet. By 1962, it had decreased to 2,300 board feet. Most of the loss occurred in the Prairie (northern) Unit where volume dropped one-third.

Survey Unit	Million board feet in— 1948	1962	Change (percent)
Prairie	4,173	2,791	-33
Claypan	3,482	3,350	- 4
Southern	2,603	2,435	- 6
Total	10,258	8,576	-16

A comparison of the number of trees in various size classes at the time of the two surveys clearly indicates why sawtimber volume is down. In 1948 nearly 29 percent of the growing-stock trees 5 inches and larger were of sawtimber size. By 1962, this figure had decreased to 23 percent.

Supply of Large, High-Quality Timber Declining

There are various criteria for measuring the overall quality of the timber resource. Among the most important are log grade, diameter class distribution, proportions of volume in desired species, and the proportion of cull trees to sound trees.

Since 1948 the number of trees 19 inches and larger has decreased nearly 24 percent, and trees 15 through 18 inches 9 percent. As a result, the volume and the proportion of sawtimber in log grades F1 and F2 have also declined (fig. 5). In 1962, only 10 percent of the sawtimber volume was found in the top two grades, a decline from the 24 percent found in 1948:

Log grade	Volume in 1962 (million bd. ft.)	Change from 1948 (percent)
F1	504	-35
F2	407	-75
F3 plus tie and timber	7,665	- 2

This does not necessarily reflect a decline in quality potential. As a general rule, a tree must be 15 inches or larger in diameter before it will produce grade F2 or better logs. So a reduction in the number of large

Figure 5.—Stands of large high-quality timber, such as the one being marked for cutting here, are becoming a rarity. (Photo courtesy of Division of Forestry, Illinois Department of Conservation.)

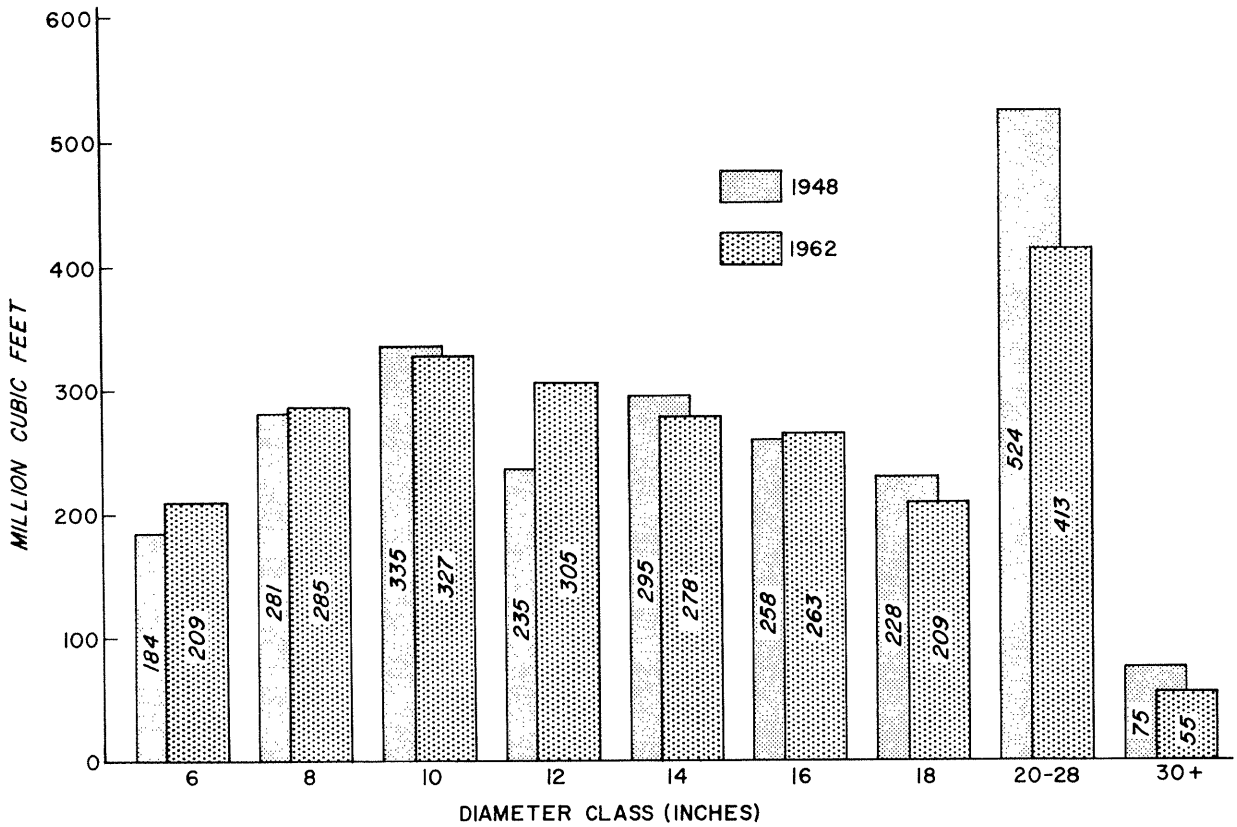

Figure 6.—Growing-stock volume by diameter class, 1948 and 1962.

trees effectively lowers log grades. There has been a substantial increase in the number of sound small trees, but their size prevents them from qualifying for the better log grades.

The decrease in the number of large sawtimber trees will affect most forest industries. The veneer, lumber, and cooperage industries depend primarily on these trees because of their yield of high-quality products and the economy in processing them. In 1962, about 20 percent of the volume was in trees 19 inches and larger (fig. 6). The previous survey found 25 percent in this class. In the period between surveys sawtimber volume dropped 1,682 million board feet, with most of the change in the larger diameter classes. The average annual decrease in the volume of trees 15 inches and larger was 116 million board feet.

Species composition of the larger trees has also been changing. The most drastic change is in the oaks and elms. Together these species accounted for two-thirds of the board-foot volume in 1948. By 1962, their volume had declined 28 percent, with the largest decrease in the white oaks (fig. 7). If the present trend continues the "other hardwoods" group will soon contain as much volume as either the white oaks or red oaks. This could be unfortunate for some forest industries unless other species can be substituted for the oaks. In 1961, almost half of the board-foot volume harvested from Illinois forests came from the white and red oak species.

The quality of Illinois' timber supply can be improved. A substantial proportion of the smaller trees

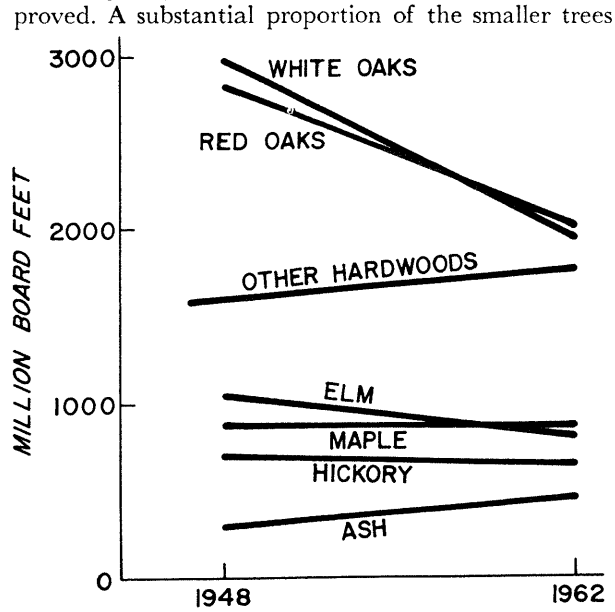

Figure 7.—Change in sawtimber volume by species group, 1948-1962.

in the stands have clean well-formed boles that eventually will produce high-quality material if they are allowed to reach maturity. In the recent survey all growing-stock trees over 2 inches in diameter were given one of several quality classifications. One of the classes, "desirable," indicated that the tree seemed to be capable of producing grade F1 or F2 logs by the time it reached maturity. Of all live trees over 2 inches in diameter, 37 percent were in this class. These desirable trees can be brought to maturity more quickly through cultural operations that will favor their development. At the present time one out of every five live trees over 5 inches in diameter is a cull. Until the large numbers of unwanted trees are reduced, quality growth will be slow.

Growth-Cut Relationship Unfavorable in the Larger Trees

Currently, the net annual growth of all growing stock exceeds the cut, but the excess of growth over cut does not extend across all diameters or across all species. Nearly 80 percent of the present annual growth, but only about 10 percent of the timber cut, occurs in trees less than 11 inches in diameter. So larger trees are sustaining most of the cut while producing only a small part of the total growth. Growth on trees 18 inches and larger is considerably less than cut. During 1962 the volume of growing stock in trees of this size was reduced 21 million cubic feet (fig. 8). The main reason for the poor growth-cut relations in these trees is a low rate of net growth due to heavy mortality (fig. 9). In some stands the volume of dead trees is greater than the volume of live trees. The Dutch elm and oak wilt diseases have taken a high toll. Recent mortality in the oaks and elms alone is greater than the mortality reported for all species in 1948 (fig. 10).

In addition, much of the excess of growth over cut is found in species that industry, as yet, uses very little. For instance, the cut of hickory is only 8 percent of growth while the cut of highly prized select white and red oaks is more than 80 percent of growth.

Although the present surplus of growth in small trees means little for industry now, it could provide the base for future industrial expansion. With proper management, Illinois forests can produce large, high-quality timber.

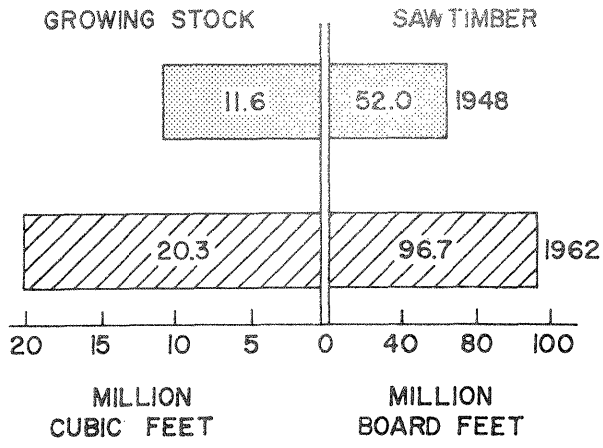

Figure 9.—Mortality of growing stock and sawtimber, 1948 and 1962.

Figure 10.—Disease has replaced fire as the primary cause of mortality in Illinois.

Forest Area Reduced Three Percent

The area of Illinois' forests has changed little in recent years. Today's forests cover 3,871,000 acres of land—3 percent less than in 1948. The northern part of the State is lightly forested, with about 6 percent of the total land area supporting trees. The proportion of land in forests gradually increases from north to south; several of the southernmost counties are more than 30-percent forested. (See generalized forest type map on the inside of back cover.)

The distribution of commercial forest land is very similar to that of total forest land (fig. 11). In 1962, commercial forest land totaled 3,761,000 acres—5 percent less than in 1948. The area of commercial forests increased in the southern part of the State but not enough to offset the losses of 260,000 acres in the north where agriculture is the primary concern of landowners. Although the number of farms in this area has been decreasing since 1940, the acreage of cropland harvested each year has been rising.

Survey Unit	Commercial forest in 1962 (thousand acres)	Change from 1948 (percent)
Prairie	1,307	−16
Claypan	1,368	+ 2
Southern	1,086	+ 5
Total	3,761	− 5

The situation is different in the southern part of the State. There the forests now occupy an additional 77,000 acres. If present trends continue, Illinois' forest industries will depend even more on these down-State forests.

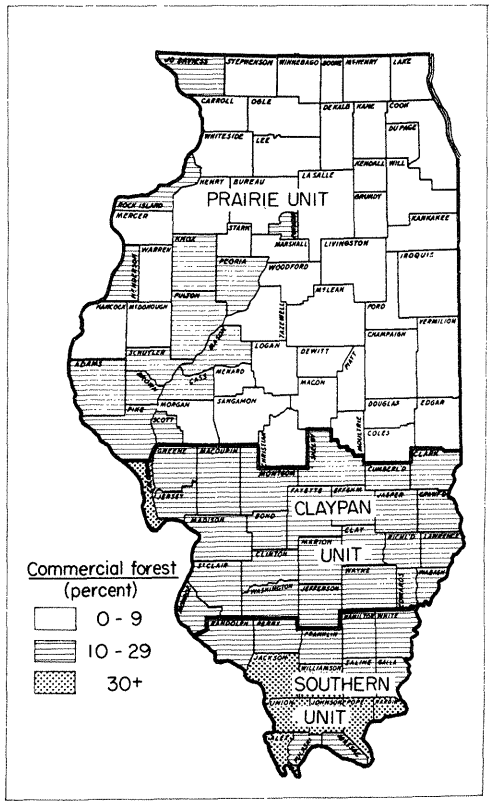

Figure 11.—Percent of land area in commercial forest by county, 1962.

The pattern of commercial forest-land ownership has changed little in recent years. Farm and miscellaneous private owners still own more than nine-tenths of all commercial forest:

Ownership	Percent owned in— 1948	1962
Private	95.2	93.2
National Forest	3.7	5.0
Other federal	.8	1.1
State	.3	.3
Forest industry	—	.4

Federal ownership has increased. On the Shawnee National Forest, land acquisition and planting has resulted in an additional 41,000 acres of commercial forest land. Nine thousand acres has been added to other federal ownership. Industry-owned forests, nonexistent in 1948, now total 17,000 acres. State-owned forest land remains nearly the same at 11,000 acres.

The 110,000 acres of forest land that are not producing commercial timber crops represent less than 3 percent of the total forest area of the State. These noncommercial forest lands are either reserved from cutting, as in parks and recreation areas, or they do not produce industrial wood products because of adverse site conditions. They do, however, contribute to the wildlife and recreation resources of the State.

PRESENT TIMBER USES

Although Illinois' timber supply is small in relation to some of the more heavily forested States, the processing of wood is a significant factor in the economy. Figures derived from the latest Bureau of Census estimates show that Illinois ranks fourth in the Nation in value added in timber-based economic activities.[1] These activities include the management of forests, and the proportion of harvesting, primary and secondary manufacturing, transportation, marketing, and construction attributed to timber. In 1958, 157,000 people were employed in these activities, and the value added by them amounted to 1.4 billion dollars. The greatest share of value added was in construction and secondary manufacturing where much of the wood used comes from outside the State. In 1958 the value of timber products harvested in Illinois was estimated at only 12.4 million dollars.[2] In this respect, Illinois ranked 34th in the United States. The low harvest value is, of course, the result of a relatively small timber cut. Down from 38 million cubic feet in 1947, the 1961 cut totaled 30 million cubic feet.

The most significant trend in timber cut is the decrease in the cut of the hard-textured hardwoods. The oaks still account for nearly half of the total harvest, but the cut of these species has dropped 5.2 million cubic feet. On the other hand, the cut of soft-textured hardwoods such as cottonwood and yellow-poplar has increased. Conifers are also being cut more heavily. Illinois has a very small volume of softwoods; yet the cut of these trees went up from 85,000 cubic feet in 1947 to 458,000 in 1961. The softwood cut, predominantly shortleaf pine, amounted to 1½ percent of the total harvest in 1961.

Production figures indicate how the timber cut is being used. The production trends discussed in the next section show to some extent the changing demand for specific products and the types of material that may be needed in the future.

Lumber Production Rising

In 1961, 43 percent of Illinois' total wood production left the woods as saw logs destined for sawmills in Illinois and adjacent States (figs. 12 and 13). Saw log production totaled 131 million board feet—an increase of 31 percent over 1947.

Approximately 1,155 Illinois mills sawed 100 million board feet of lumber in 1947. By 1961, the number of active mills had dropped to 314, but their output increased to 122 million board feet. That year two mills produced more than 3 million board feet of lumber. Another 106 mills reported outputs ranging from 50,000 to 500,000 board feet. Most of the remaining mills produced less than 50,000 board feet. Lumber production has continued to rise steadily in recent years, reaching 138 million board feet in 1963 according to the Bureau of the Census.

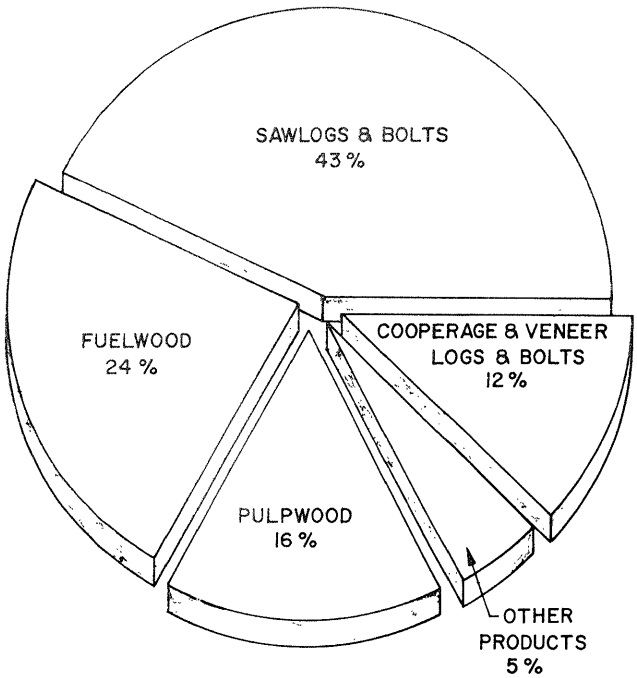

Figure 12.—Percent of total cubic-foot output of timber products by product, 1961.

Pulpwood Production Up

The increasing demand for hardwood pulpwood could provide part of the impetus that forest owners need to improve their stands. Large areas of forest land need thinning and other cultural treatment, but there are few markets for the small and low-grade material removed in timber stand improvement.

Illinois is the second largest producer of pulpwood in the Central States, and the largest producer of soft hardwood pulpwood. Production has been rising rapidly (fig. 14). Since the previous survey in 1947, the harvest of pulpwood from the State has increased 2½ times. Nearly 100,000 cords were cut in 1961. Later statistics show that production continued to rise in 1962, then dropped back in 1963. But the general trend is upward and if this continues, pulpwood will soon rank second to saw logs in volume taken from the forests. Pulpwood made up 16 percent of the total wood production in 1961.

Most of the pulpwood harvested from Illinois is used in the manufacture of felt, board, and corrugating medium. The combined pulping capacity of the State's eight pulpmills is 720 tons a day.[3]

Figure 14.—Pulpwood production has become increasingly important in recent years.

Cooperage Log Production Up But Future Uncertain

The Central States Region is the leading cooperage-log producing area in the United States. In 1962 the Region produced one-third of the national output. In Illinois the cut of cooperage logs is considerably higher now than it was in 1947; yet recent trends make the future somewhat questionable. In 1962 manufacturers of tight cooperage were concerned over proposals that would permit bourbon barrels to be used several times. Present Federal regulations prohibit the re-use of these barrels. Producers of slack cooperage are also hesitant about increasing produc-

tion because their markets are being taken over by newer packaging materials. Illinois cooperage - log production reflected this uncertainty, dropping 9 percent between 1960 and 1962; but the decline was not as great as in some of the other Central States. In the Region, Illinois ranks second only to Missouri in the production of cooperage logs. In 1962 output totaled 25 million board feet—an increase of 44 percent over that of 1947.

In addition to being one of the top producers of cooperage, Illinois has the largest output of container veneer logs in the Central States. Six of the State's eight veneer mills produce containers for fruits, vegetables, and meats. They utilize several soft-textured hardwood species, the primary one being cottonwood. The other two mills manufacture high-quality face veneer, mainly from walnut logs.

The production of veneer logs and bolts in Illinois dropped between 1947 and 1958. Then in 1960 production climbed to 11.8 million board feet—slightly higher than the output in 1947. In 1963 production was 9.2 million board feet—22 percent below that of 1960. This recent sharp decline in part reflects increased competition from fiber containers.

Less Fuelwood Used

Fuel oil, coal, and gas are rapidly replacing wood as a source of fuel in rural homes. Not long ago fuelwood accounted for about half of the total wood production from Illinois' forests. The 1961 fuelwood production of around 150,000 cords is less than half that cut in 1947 and represents only a quarter of the total wood production.

FUTURE TIMBER SUPPLY

During the next 30 years the cut of timber products from Illinois will probably rise to keep pace with the needs of a growing population. But if intensity of forest management continues to advance at the rate indicated by recent trends, increases in productivity will be more than enough to offset expanded cutting rates. The net annual growth projected for 1992 is almost 150 million cubic feet, or 74 percent more than at present. Timber cut is expected to increase 64 percent to almost 50 million cubic feet per year during the same period. The steady increase in growth over cut would double the volume of growing stock by 1992.

Though substantial, the projected increases in productivity are small when compared with the potential of Illinois' forests. Under present management know-how it is estimated that 281 million cubic feet of wood could be grown each year. This is approximately three times the present growth rate. One-third of the commercial forest land has the inherent capacity to produce more than 85 cubic feet of wood per acre per year. This land, in itself, could grow more wood than the total growth reported for all commercial forest land in 1962.

The decreasing supply of sawtimber trees is a critical problem that must be faced in the near future. These large high-value trees make up most of the volume sought by the present forest industries. As noted before, growth has not been equal to cut in the larger diameter classes. A large part of the present sawtimber volume is in sawtimber stands that have been cut over several times and are now well past their prime. Past cutting has generally left the poorer trees. Not only culls but a large number of defective growing-stock trees that will produce only low-grade material have been left. Quality growth in these stands is slow and far from that needed to supply future demands of present industries.

Annual mortality is also high in the older stands. Sawtimber mortality averaged 26 board feet per acre in 1962—double the death rate in 1948. Insects and disease are responsible for nearly two-thirds of the current mortality.

High-grading in the older stands, plus a high mortality rate, has reduced sawtimber growth substantially from what it was in 1948. So even though growth in the younger trees has been rapid, total growth per acre is the same today as it was at the time of the last survey (23 cubic feet per acre).

About 175,000 Acres Should Be Cut Annually

If growing stock that provides little or no increment to the stands were removed, about 386,000 acres of over-mature commercial forests could be cut in the next 10 years. Also, stands on about 53,000 acres are reaching rotation age each year. These stands

have passed their peak productivity and should be cut before mortality and decay reduce the usable volume sufficiently to make harvesting uneconomical. In addition, timber stand improvement work is needed in younger stands to favor the better trees. Although the growth rate in the young stands is adequate, a large part of the growth is going on trees that have few markets. Many trees reaching sawtimber size are either of low quality or are species little used today. Stand improvement measures are needed on approximately 82,000 acres of commercial forest land annually.

The acreage recommended for cutting annually during the next decade is summarized below:

Forest type group	Thousand acres by type of cut		
	Emergency	Harvest	Intermediate
Pine	—	—	1.1
Upland hardwoods	29.3	29.4	50.1
Lowland hardwoods	9.3	23.3	30.8
Total	38.6	52.7	82.0

Recommended Volume Cut is Four Times the Current Harvest

The cut recommendations outlined in the preceding section would result in an annual desirable cut of 112 million cubic feet. This exceeds the current annual timber cut by about 82 million cubic feet. The desirable cut of sawtimber exceeds the actual cut by 275 million board feet annually.

The term "desirable cut" is used to describe the volume of timber that could be cut annually from the forests while bringing the stands to a more productive condition. It assumes that all lands would be handled in like manner regardless of individual owner preference. Although theoretical, desirable cut figures do show the cut that the forests could sustain under management practices such as are used on the National Forests. Presented by species and survey unit, desirable cut estimates are useful in pointing out the areas where more timber could be removed and the species that would provide this cut.

A comparison of actual cut with desirable cut indicates that only a few species are in short supply. Although the cut of "other softwood" growing stock can be expanded, shortleaf pine is overcut now, especially in sawtimber-size trees. Actual cut of shortleaf pine exceeded desirable cut by 2 million board feet in 1961. Cottonwood is another species in great demand, especially for container veneer. Here the deficit was 10 million board feet. Nearly all of the remaining species can sustain additional cutting.

About 42 percent of the surplus of desirable cut over actual cut occurs in the Claypan Unit. The remainder is nearly equally divided between the Prairie and Southern Units.

The immediate result of removing 112 million cubic feet (the desirable cut) each year would be a reduction in the growing-stock volume. For several years growth would be less than cut (fig. 15). The reduction would be less severe each year because of increased growth brought about by improvement cutting on some 82,000 acres annually. At the end of approximately 11 years annual growth would again be equal to cut, and the reduction of growing stock would cease. The 386,000 acres of over-mature timber would have been removed and 527,000 acres would have reached rotation age and have been harvested. Improvement cutting on 820,000 acres would have taken place, with increased growth on the more desirable trees.

As growth continued to exceed cut, the growing-stock volume would climb. By the end of the second 10-year period it would be nearly up to its former level in 1961. From this point on, the cut could be maintained at a slightly lower level than growth until the desired growing-stock volume is reached. Timber quality would be much improved and the harvest consequently more valuable.

The recommended cut for sawtimber would have to be modified in the second 10-year period as shown in figure 16. Sawtimber volume, as with growing stock, would decrease the first period. It would continue to decrease throughout the second period unless the cut is reduced.

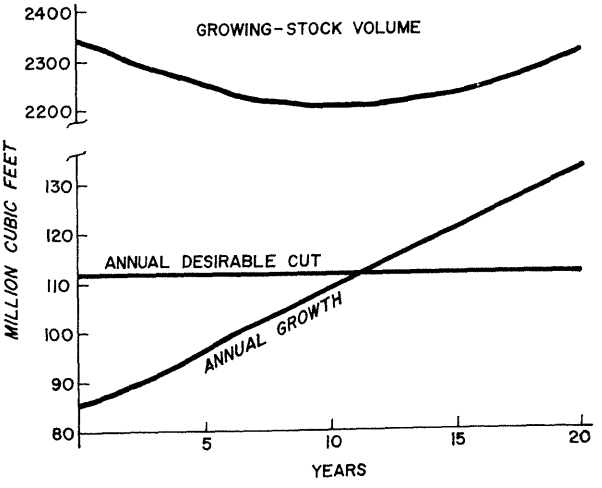

Figure 15.—Projections of growing-stock volume and growth, assuming the desirable cut is made.

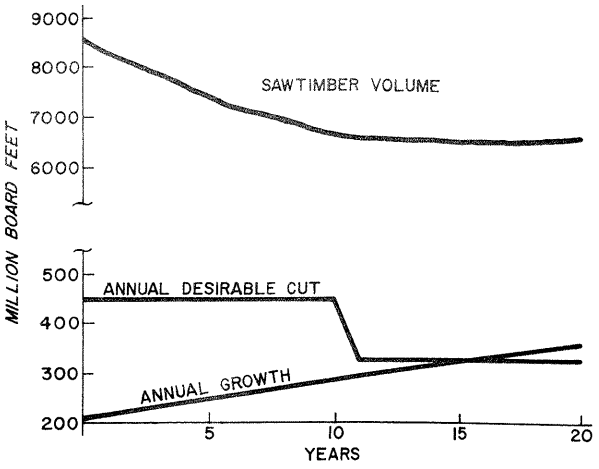

Figure 16.—Projections of sawtimber volume and growth, assuming the desirable cut is made.

More Markets Needed for Small and Low-Grade Timber

Although the forests can yield a much larger harvest than they do, markets for the material that should be cut are hard to find. A good part of the desirable cut ought to come from low-quality trees and from species that are not normally used by the present forest industries. Nearly 30 percent of the sawtimber surplus is in the hickories and miscellaneous hardwoods. In addition, about 28 percent of the desirable cut should come from low-quality pole-timber trees.

If harvesting the desirable cut of 112 million cubic feet is to be a commercial undertaking, new markets will have to be developed or existing processes modified to utilize small and low-grade timber. A stable market for small trees would certainly provide incentive to owners with stands that need thinning. Expanding local pulpmills use a wide variety of species; and some low-grade hardwoods that were unmerchantable a few years ago are now being pulped. However, this is only one industrial outlet, and its needs are not large enough to take all the low-quality trees that should be cut. Further research is needed, both in development of new products and adaptation of the present timber supply to existing products.

Figure 17.—Most of the timber harvest comes from small privately owned woodlands.

Private Owners Determine Management

Actions taken by the many private landowners will largely determine the future wood supply. More than 90 percent of the State's commercial forest land is in tracts owned by farmers, doctors, lawyers, housewives, and many others—people who are not primarily concerned with growing timber. In 1961 their woodlots provided 96 percent of the total timber harvest (fig. 17).

These private lands could sustain a much higher growth rate. Present net annual growth is only 22 cubic feet per acre. This low growth rate is the result of little or no management. Although technical assistance is available from the Forestry Division of the Illinois Conservation Department and others, only a small proportion of owners show an interest in forest management. The result has been a high-grading of the woodlots. The better trees have been cut, leaving a large number of cull and defective trees. Illinois' forests have little chance of realizing their full potential unless the many private landowners are persuaded to put forestry to work.

APPENDIX

Forest Survey Methods

Area, Volume, and Growth

Estimates of area and volume on the Shawnee National Forest were supplied by the North Central Region of the U.S. Forest Service. The Shawnee contains 5.3 percent of the forest land in the State.

The remaining forest land was surveyed by the Lake States Forest Experiment Station. Estimates of forest area were based on classification of 272,968 points systematically spaced on aerial photographs. The points were first classified as either forest or nonforest. One-fourth of the forest points were further classified under the stereoscope to provide a breakdown of forest area into type and stand-size classes. A final ground check of 5,261 points was made to adjust the photo classifications. Adjustment is usually necessary because of changes in land use between the time of photography and the survey.

The ground check points were also used to estimate forest volume and growth. Variable-radius plots with a basal area factor of 37.5 were taken on 549 of the points classified as commercial forest by the fieldmen.

Timber Cut

Production surveys and utilization studies provided the basis for timber cut estimates. All sawmills, veneer mills, pulpmills, and other wood-using industries were canvassed. The total timber cut computed from this canvass was broken down by Survey unit on the basis of stumps of recently cut trees tallied by the inventory field crews. The stump tally was also used to determine the proportion of timber cut by diameter classes.

Desirable Cut

Desirable cut is the volume of timber that would be cut on commercial forest land during a given period under specified management plans for sustained production, such as those in effect on National Forests. It is based on the actions considered necessary to increase growth and build up the growing stock to a desirable quantity and quality. The general computing procedure was as follows:

1. Stands past rotation age were scheduled to be cut within the next 10 years—one-tenth of the total each year.
2. For stands reaching rotation age, harvest-cut acreage was computed by forest type. The area between rotation age and one-half rotation age was divided by one-half the rotation age to determine the area to be cut annually.
3. Estimates of volume for the acres designated for cutting in steps 1 and 2 were then computed by expanding appropriate survey plot volumes.
4. Additional desirable cut volume was estimated for areas that need some form of cultural operation such as thinning or cleaning. A stand must have been able to yield at least 3 cords of usable wood in the improvement operation before it was recommended for treatment.

Accuracy of Forest Survey Estimates

Survey estimates are subject to two types of error. Sampling error occurs because it is impractical to measure every tree in the forest. A small number of trees are carefully measured and their volumes are expanded to represent the total volume. The variation of this sample is measurable and provides the basis for the calculated sampling error. The second type of error cannot be measured. It consists of errors in measurement, arithmetic, recording, etc. This is kept to a minimum by training, supervision, and checking of all phases of the work.

The estimate of 3,871,300 acres of forest land in Illinois has a sampling error of 2.36 percent or 91,360 acres. This means that with repeated surveys the estimate of total forest area would fall within the range of 3,779,940 acres to 3,962,660 acres, two out of three times. The sampling error for total commercial forest land is 2.80 percent, that for total cubic-foot volume

is 3.21 percent, and that for total board-foot volume is 2.97 percent. As these totals are broken down by forest type, species, ownership, and diameter classes, sampling errors increase—the smaller the unit the higher the sampling error. Table I presents sampling errors for different size units of volume and commercial forest area.

The timber cut from growing stock (estimated at 30 million cubic feet) has a sampling error of approximately 13.9 percent, or a plus or minus 4.2 million cubic feet.

Merchantable volume in the upper stem portion of hardwood sawtimber trees was not included in the estimates of growing-stock volume for 1948. The 1962 data does include this material. Original 1948 volumes had to be adjusted before comparisons between the two surveys could be made.

Table I.—*Guide for judging accuracy of area and volume, Illinois, 1962*

Sampling error	Commercial forest land	Sawtimber volume	Growing-stock volume
Percent	*Thousand acres*	*Million bd. ft.*	*Million cu. ft.*
2.8	3,761	—	—
3.0	3,284	8,576	—
3.2	2,886	7,373	2,344
4.0	1,847	4,719	1,512
5.0	1,182	3,020	967
10.0	296	755	242
20.0	74	189	60
40.0	19	47	15
100.0	3	8	2

Definition of Terms

Land-Use Classes

Land area.—The area of dry land and land temporarily or partially covered by water such as marshes, swamps, and flood plains, streams, sloughs less than 1/8 mile wide, and lakes, reservoirs, and ponds less than 40 acres in area.

Forest land.—Land at least 10-percent stocked by forest trees of any size, or formerly having such tree cover, and not currently developed for nonforest use.
Commercial forest land.—Forest land that is producing or capable of producing crops of industrial wood and not withdrawn from timber utilization by statute or administrative regulation.

Noncommercial forest land.—All other forest land that does not qualify as commercial forest: (1) unproductive—forest land incapable of yielding crops of industrial wood because of adverse site conditions, and (2) productive reserved—forest land capable of producing crops of industrial wood but withdrawn from timber utilization through statute or administrative regulation.

Nonforest land.—Land that has never supported forests and land formerly forested where forest use is now precluded by development for nonforest use.

Forest Types

Forest type classification is based on the stocking of all live dominant and codominant trees. The following types are used in this report:

White-red-jack pine.—Forests in which 50 percent or more of the stocking is eastern white pine, red pine, or jack pine, singly or in combination.

Loblolly-shortleaf pine.—Forests in which 50 percent or more of the stocking is loblolly, shortleaf, or other southern yellow pines, singly or in combination. This type includes only shortleaf pine in Illinois.

Oak-pine.—Forests in which 50 percent or more of the stocking is hardwoods (usually upland oaks) but in which pines comprise 25 to 49 percent of the stocking.

Oak-hickory.—Forests in which 50 percent or more of the stocking is upland oaks or hickories, singly or in combination, except stands that classify as oak-pine.

Oak-gum-cypress.—Bottomland forests in which 50 percent or more of the stocking is tupelo, blackgum, sweetgum, oaks, or cypress, singly or in combination, except stands that classify as oak-pine.

Elm-ash-cottonwood.—Forests in which 50 percent or more of the stocking is elm, ash, or cottonwood, singly or in combination.

Maple-beech-birch.—Forests in which 50 percent or more of the stocking is maple, beech, or yellow birch, singly or in combination.

Aspen-birch.—Forests in which 50 percent or more of the stocking is aspen or paper birch, singly or in combination.

Stocking

Stocking describes how well the available growing space is being utilized by trees. Ten points on each ground plot were used to determine stocking. If two dominant or codominant growing-stock trees formed a closed canopy over a point, the point was considered stocked. Twenty trees tallied in this way would indicate 100-percent stocking, 10 trees 50-percent, etc.

Stand-Size

Stand-size is a classification of forest land based on the predominant size of timber present: sawtimber, poletimber, or saplings and seedlings.

Sawtimber stands.—Stands at least 10-percent stocked with growing-stock trees, with half or more of this stocking in sawtimber or poletimber trees and with sawtimber stocking at least equal to poletimber stocking.

Poletimber stands.—Stands at least 10-percent stocked with growing-stock trees and with half or more of this stocking in sawtimber and/or poletimber trees and with poletimber stocking exceeding that of sawtimber.

Sapling-seedling stands.—Stands at least 10-percent stocked with growing-stock trees and with saplings and/or seedlings comprising more than half of the stocking.

Nonstocked areas.—Commercial forest land less than 10-percent stocked with growing-stock trees.

Stand Age

Age of the main stand for both even and uneven-aged stands expressed in years.

Site Class

Site class is an indication of what the stands can produce when fully stocked with desirable trees. It is based on the potential yields in cubic feet per acre of mean annual growth at culmination of increment. In this survey, site index (height of dominant and codominant trees at 50 years of age) was used to estimate site class. Stands with site index of 70 or more were assumed to have a productivity of 85 cubic feet or more per acre per year; site index of 50 to 70 a productivity of 50 to 85 cubic feet; and site index of 35 to 50 a productivity of less than 50 cubic feet. Stands with site index less than 35 were considered unproductive.

Area Condition Class

Area condition is the classification of commercial forest land based upon stocking of desirable trees and other conditions affecting current and prospective timber growth.

Desirable.—Areas 70-percent or more stocked with desirable trees.

Moderate and favorable.—Areas 40- to 70-percent stocked with desirable trees and with less than 30 percent of the area having undesirable growing-stock trees, cull trees, inhibiting vegetation, slash, or non-stockable conditions that prevent occupancy by desirable trees.

Moderate and unfavorable.—Areas 40- to 70-percent stocked with desirable trees and with 30 percent or more of the area having other trees or conditions that prevent occupancy by desirable trees.

Poor but favorable. — Areas less than 40-percent stocked with desirable trees, but having an adequate seed source and seedbed favorable to natural regeneration.

Poor and unfavorable.—Areas less than 40-percent stocked with desirable trees, and having an inadequate seed source or seedbed unfavorable to natural regeneration.

Tree-Quality Classes

Growing-stock trees.—All live sawtimber, poletimber, sapling and seedling trees. Cull trees are not considered growing stock.

Desirable trees.—Growing-stock trees that have no serious defects in quality limiting present or prospective use; are of relatively high vigor; and contain no pathogens that may result in death or serious deterioration before rotation age. These are the trees that would be favored in silvicultural operations.

Acceptable trees.—Growing-stock trees that do not qualify as desirable trees.

Cull trees.—Live trees that do not contain at least one 8-foot saw log now or prospectively because of limbiness, crook, or rot. Trees with no commercial use are also classified as cull.

Salvable dead trees.—Standing or down dead trees that are considered currently or potentially merchantable.

Tree-Size Classes

Sawtimber trees.—Live trees of commercial species at least 9 inches in diameter for softwoods and 11 inches in diameter for hardwoods, and containing at least one 8-foot saw log meeting the minimum log grade or tie and timber specification.

Poletimber trees.—Live trees of commercial species at least 5 inches in diameter but smaller than sawtimber size, and of good form and vigor.

Saplings and seedlings.—Live trees of commercial species less than 5 inches in diameter and of good form and vigor.

Diameter

D.b.h. (diameter at breast height).—Tree diameter in inches measured outside the bark at a point 4½ feet above the ground.

Diameter class.—Trees are measured to the nearest 0.1 inch in the field and reported by 2-inch classes. The 6-inch class, for example, includes trees from 5.0 inches through 6.9 inches.

Volume

Growing-stock volume. — Cubic volume of sound wood in the central stem of live sawtimber and poletimber trees from stump to a minimum 4-inch top diameter outside bark or to the point where the central stem breaks into limbs.

Sawtimber volume.—Net volume of the saw-log portion of live sawtimber trees in board feet, International ¼-inch rule. The saw-log portion extends from stump to a minimum top diameter outside bark of 6 inches for softwoods and 8 inches for hardwoods or to the point where defects reduce saw-log quality below Standard Log Grade 3 or Tie and Timber Grade.

All timber volume.—Cubic-foot volume of sound wood in the bole of growing stock, cull, and salvable dead trees 5 inches or larger in diameter, from stump to a minimum 4-inch top diameter outside bark or to the point where the central stem breaks into limbs.

Growth

Net annual growth of growing stock.—The annual change in volume of sound wood in live sawtimber and poletimber trees and the total volume of trees entering these classes through ingrowth, less volume losses resulting from natural causes on commercial forest land.

Growing-stock growth.—Net annual growth of poletimber and sawtimber trees in cubic feet.

Sawtimber growth.—Net annual growth of sawtimber trees in board feet, International ¼-inch rule.

Mortality

Mortality of growing stock.—Cubic-foot volume of sound wood in live sawtimber and poletimber trees dying annually from natural causes.

Mortality of sawtimber.—Net board-foot volume of sawtimber trees dying annually from natural causes.

Timber Cut

Annual cut of growing stock.—Cubic-foot volume of sound wood in live sawtimber and poletimber trees cut for forest products during a specified year, including both roundwood products and logging residues.

Annual cut of sawtimber.—Net board-foot volume of live sawtimber trees cut for forest products during a specified year, including both roundwood products and logging residues.

Timber products output.—Net volume of rough forest products cut from growing stock, cull trees, dead trees, limbwood, and plant by-products.

Logging residues.—Net volume of live sawtimber and poletimber trees cut or killed by logging on commercial forest land and not converted to timber products.

Desirable Cut

Annual desirable cut.—The net volume of live sawtimber and poletimber trees that can be cut annually during the next 10 years in commercial-logging operations while maintaining or increasing growing stock and while effecting a reasonably even distribution of age classes below the rotation age selected for each type. It includes harvest and improvement cuts yielding 3 cords or more per acre, and one-tenth of the entire net volume of stands beyond the rotation age.

Log Grade

Log grades used in Illinois are shown in tables II, III, and IV.

Table II.--Specifications for hardwood factory lumber logs

Grading factors	Log grade F1		Log grade F2	Log grade F3
	Butts only	Butts and uppers	Butts and uppers	Butts and uppers
Diameter (min.)	13-15"	16-19":20"+	11"	8"+
Length (min.)	10'+	10'+	8-11':12'+	8'+
Clear cuttings (on the 3 best faces):				
Length (min.)	7'	5' : 3'	3'	2'
Number on face (max.)	2	2	2 : 3	Unlimited
Yield in face length (min.)	5/6	5/6	4/6	3/6
Sweep and crook deduction (max.)	15%	15%	30%	50%
Cull deduction, including sweep (max.)	40%	40%	50%	50%
Sound end defects, area (max.)	See instructions			

Exceptions.--In ash and basswood 12" d.i.b. for grade 1 butts.

Grade 2 10" d.i.b. must be grade 1 surface quality.

Grade 2 11" d.i.b. limited to two cuttings.

Grade 2 8' and 9' lengths limited to 12" d.i.b.; 3/4 yield in not more than 2 3'+ cuttings.

Sweep and crook allowance reduced 1/3 in logs with more than 1/4 diameter in sound end defects.

Sixty percent cull deduction permitted in grade 2, if otherwise of grade 1 quality.

Sixty percent cull deduction permitted in grade 3, if otherwise of grade 2 quality.

Source: Hardwood Log Grades for Standard Lumber, Forest Products Laboratory, 1953.

Table III.--Specifications for tie and timber logs

Position in tree	Butt and upper
D.i.b., small end, inches	8"+
Length without trim, feet	8'+
Clear cuttings	No requirements. Not graded on cutting basis.
Sweep allowance, maximum	1/4 d.i.b. of small end for half logs and 1/2 d.i.b. for log 16' long.
Sound surface defects permitted:	
Single knots	Any number, if none has an average collar diameter in excess of 1/3 of log diameter at point of occurrence.[1/]
Whorled knots	Any number, provided the sum of the collar diameters does not exceed 1/3 the log diameter at point of occurrence.
Holes	Any number not exceeding knot specifications if they do not extend over 3 inches into the contained tie or timber.
Unsound defects permitted:	
Surface	Any number and size if they do not extend into contained tie or timber, If they extend into contained tie and timber they shall not exceed size, number, and depth of limits of sound knots.
Interior	None permitted except one shake not more than 1/3 the width of contained tie or timber and one split not over 5 inches long.

1/ Knot collar is the average of the vertical and horizontal diameters of the limb or knot swelling as measured flush with the surface of the log.

Note: Local use logs that do not meet the minimum specifications of the above grades will not be considered merchantable for survey purposes.

Source: Forest Survey Instructions, Section 4810, Forest Service Handbook.

Table IV.--Specifications for southern pine logs

Grade	D.I.B.	Length	Surface requirements
1	10" - 16"	8' plus	Surface clear (not considering adventitious knots and branches).
	16" plus	8' plus	Not more than three 2- to 4-inch knots and any number of smaller knots
2	8" - 9"	8' plus	Surface clear
	10" - 13"	8' plus	Any number of small knots (less than 2 inches in diameter).
	14" plus	8' plus	Not more than six 2- to 4-inch knots and any number of smaller knots
3	6" - 7"	8' plus	Any number of small knots not exceeding 1 inch in diameter.
	8" - 13"	8' plus	With not more than six 2- to 4-inch knots.
	14" plus	8' plus	More than six 2- to 4-inch knots. Any log with one or more knots 5 inches and larger.

Knotty or crooked merchantable logs 8-inch d.i.b. or over that do not fall in either No. 1 or No. 2 grade: length 10 feet or over.

Source: adapted from log grades defined in USDA Tech. Bul. 861. "Financial aspects of selective cutting in the management of second-growth pine-hardwood forests west of the Mississippi River" by R. R. Reynolds, W. E. Bond, and Burt P. Kirkland, June 1944. 118 pp. illus.

Principal Commercial Tree Species[1] of Illinois

SOFTWOOD SPECIES

Shortleaf and loblolly pine group includes—
- Shortleaf pine (no loblolly pine found in Illinois) *Pinus echinata* Mill.

Cypress — *Taxodium distichum* (L.) Rich.

Redcedar — *Juniperus virginiana* L.

Other softwoods
- White pine — *Pinus strobus* L.
- Any softwood not shown above

HARDWOOD SPECIES

Select white oak group includes—
- Bur oak — *Quercus macrocarpa* Michx.
- Chinkapin oak — *Q. muehlenbergii* Engelm.
- Swamp chestnut oak — *Q. michauxii* Nutt.
- Swamp white oak — *Q. bicolor* Willd.
- White oak — *Q. alba* L.

Select red oak group includes—
- Cherrybark oak — *Q. falcata* var. *pagodaefolia* Ell.
- Northern red oak — *Q. rubra* L.
- Shumark oak — *Q. shumardii* Buckl.

Other white oak group includes—
- Overcup oak — *Q. lyrata* Walt.
- Post oak — *Q. stellata* var. *stellata* Wangenh.

Other red oak group includes—
- Black oak — *Q. velutina* Lam.
- Blackjack oak — *Q. marilandica* Muenchh.
- Pin oak — *Q. palustris* Muenchh.
- Scarlet oak — *Q. coccinea* Muenchh.
- Shingle oak — *Q. imbricaria* Michx.
- Southern red oak — *Q. falcata* Michx.
- Water oak — *Q. nigra* L.
- Willow oak — *Q. phellos* L.

Select hickory group includes—
- Mockernut hickory — *Carya tomentosa* Nutt.
- Shagbark hickory — *C. ovata* (Mill.) K. Koch
- Shellbark hickory — *C. laciniosa* (Michx. f.) Loud.

Other hickory group includes any hickory not shown above

Hard maple group includes—
- Black maple — *Acer nigrum* Michx. f.
- Sugar maple — *A. saccharum* Marsh.

Beech (American) — *Fagus grandifolia* Ehrh.

Black walnut — *Juglans nigra* L.

Ash — *Fraxinus sp.*

Elm — *Ulmus sp.*

Soft maple group includes—
- Boxelder — *Acer negundo* L.
- Red maple — *A. rubrum* var. *rubrum* L.
- Silver maple — *A. saccharinum* L.

Sweetgum — *Liquidambar styraciflua* L.

Tupelo and black gum group includes—
- Black tupelo — *Nyssa sylvatica* Marsh.
- Water tupelo — *N. aquatica* L.

Cottonwood — *Populus deltoides* Bartr.

Aspen (quaking) — *P. tremuloides* Michx.

Sycamore (American) — *Platanus occidentalis* L.

Yellow-poplar — *Liriodendron tulipifera* L.

Basswood (American) — *Tilia americana* L.

Other soft hardwoods group includes—
- Birch, river — *Betula nigra* L.
- Buckeye — *Aesculus* sp.
- Butternut — *Juglans cinerea* L.
- Catalpa, northern — *Catalpa speciosa* Warder
- Cherry, black — *Prunus serotina* Ehrh.
- Hackberry — *Celtis occidentalis* L.
- Kentucky coffeetree — *Gymnocladus dioicus* (L) K. Koch
- Magnolia (cucumbertree) — *Magnolia acuminata* L.
- Sugarberry — *Celtis laevigata* Willd.
- Willow — *Salix* sp.

Other hard hardwoods group includes—
- Dogwood, flowering — *Cornus florida* L.
- Honeylocust — *Gleditsia triacanthos* L.
- Locust, black — *Robinia pseudoacacia* L.
- Osage-orange — *Maclura pomifera* (Raf.) Schneid.
- Persimmon, common — *Diospyros virginiana* L.

TABLES

Area

1. Land area by classes and survey units.
2. Area of commercial forest land, by ownership classes and survey units.
3. Area of commercial forest land, by stand-size and ownership classes.
4. Area of commercial forest land, by forest types and survey units.
5. Area of commercial forest land, by sawtimber volume and stand-size classes.
6. Area of commercial forest land, by stocking classes based on alternative stand components.
7. Area of commercial forest land, by stocking classes of growing-stock trees and by stand-size classes.
8. Area of commercial forest land, by area-condition and ownership classes.
9. Area of commercial forest land, by sites and ownership classes.
10. Area of commercial forest land, by forest types and ownership classes.
11. Area of commercial forest land, by forest types and site classes.
12. Area of commercial forest land, by forest types and stand-age classes.
13. Area of noncommercial forest land, by forest types.
14. Area of commercial forest land, by forest types and area-condition classes.
15. Area of land and forest land, by counties.

Number of Trees

16. Number of growing stock trees on commercial forest land, by species and diameter classes.
17. Number of cull and salvable dead trees on commercial forest land, by species and diameter classes.

Volume of Standing Trees

18. Volume of timber on commercial forest land, by tree and species classes.
19. Volume of growing stock and sawtimber on commercial forest land, by ownership and species classes.
20. Volume of growing stock and sawtimber on commercial forest land, by stand-size and species classes.
21. Volume of growing-stock trees on commercial forest land, by species and diameter classes.
22. Volume of sawtimber on commercial forest land, by species and diameter classes.
23. Volume of growing stock on commercial forest land, by species and survey units.
24. Volume of sawtimber on commercial forest land, by species and survey units.
25. Volume of sawtimber on commercial forest land, by species and log grades.
26. Volume of salvable dead sawtimber-size trees on commercial forest land, by species.
27. Volume of growing stock on commercial forest land, by species, 1948 and 1962.
28. Volume of sawtimber on commercial forest land, by species, 1948 and 1962.
29. Volume of growing stock and sawtimber on commercial forest land, by counties and species classes.

Growth and Mortality

30. Net annual growth of growing stock on commercial forest land, by species and survey units.
31. Net annual growth of sawtimber on commercial forest land, by species and survey units.
32. Annual mortality of growing stock and sawtimber on commercial forest land, by species.
33. Annual mortality of growing stock and sawtimber on commercial forest land, by ownership and species classes.
34. Annual mortality of growing stock and sawtimber on commercial forest land, by causes and species classes.

Timber Cut and Timber Products

35. Annual timber cut from growing stock on commercial forest land, by species and survey units.

36. Annual timber cut from live sawtimber on commercial forest land, by species and survey units.

37. Total output of timber products, by type of material used and species classes.

38. Total output of roundwood products, by source and species classes.

39. Number of primary wood-using plants, by survey units.

40. Annual timber cut from growing stock on commercial forest land, by species, 1947 and 1961.

41. Annual timber cut from growing stock on commercial forest land, by products and logging residues and species classes.

42. Annual timber cut from live sawtimber on commercial forest land, by products and logging residues and species classes.

43. Volume of unused plant residues, by industrial sources and type of residue, and by species classes.

Desirable Cut

44. Annual desirable cut of growing stock on commercial forest land, by species and survey units.

45. Annual desirable cut of live sawtimber on commercial forest land, by species and survey units.

Comparison of Growth, Cut, and Desirable Cut

46. Net annual growth, annual cut, and desirable cut of growing stock on commercial forest land, by species classes and by ownership classes.

47. Net annual growth, annual cut, and desirable cut of sawtimber on commercial forest land, by species classes and by ownership classes.

48. Surplus and shortage in growing stock and sawtimber, by species and survey units.

Growth Projections

49. Timber growth projections, 1962 and 1992.

Table 1.--Land area by classes and Forest Survey units, Illinois, 1962

(In acres)

Land class	All units	Prairie	Claypan	Southern
Forest land:				
Commercial forest	3,761,400	1,307,200	1,368,200	1,086,000
Unproductive forest	65,000	13,100	19,900	32,000
Productive-reserved forest	44,900	29,600	4,700	10,600
Total forest land	3,871,300	1,349,900	1,392,800	1,128,600
Nonforest land:				
Cropland	23,863,600	-	-	-
Pasture and range	3,321,100	-	-	-
Other	4,739,200	-	-	-
Total nonforest land[1/]	31,923,900	22,026,700	7,092,300	2,804,900
All land[2/]	35,795,200	23,376,600	8,485,100	3,933,500

1/ Includes 170,600 acres of water according to Survey standards of area classification but defined by Bureau of the Census as land.

2/ From U.S. Bureau of the Census, Land and Water Area of the United States, 1960.

Table 2.--Area of commercial forest land, by ownership classes and Forest Survey units, Illinois, 1962

(In acres)

Ownership class	All units	Prairie	Claypan	Southern
National Forest[1/]	187,800	-	-	187,800
Other Federal	41,500	17,500	4,000	20,000
State	11,100	6,000	1,100	4,000
Forest industry (lumber)	16,700	5,300	600	10,800
Farmer-owned	2,216,000	938,900	793,800	483,300
Miscellaneous private	1,288,300	339,500	568,700	380,100
All ownerships	3,761,400	1,307,200	1,368,200	1,086,000

1/ All commercial forest acreage is operable.

Table 3.--Area of commercial forest land, by stand-size and ownership classes, Illinois, 1962

(In acres)

Stand-size class	All ownerships	National Forest	Other public	Forest industry	Farmer and miscellaneous private
PRAIRIE UNIT					
Sawtimber	817,500	-	7,800	5,300	804,400
Poletimber	313,100	-	11,800	-	301,300
Sapling and seedling	166,800	-	-	-	166,800
Nonstocked	9,800	-	3,900	-	5,900
All classes	1,307,200	-	23,500	5,300	1,278,400
CLAYPAN UNIT

1/ The outlook for timber volumes, growth and cut to 1992 is based on assumptions that: (1) Annual timber production in the United States and Illinois will rise with estimated increases in population and national income; (2) wood will maintain its relative position in the national economy; (3) forestry will continue to advance at the rate indicated by recent trends, and (4) Illinois' proportion of the wood market will increase somewhat. The assumed trends anticipate continuing reforestation, "thickening up" of natural stands, improved cutting practices and forest managment, and other changes leading to a more productive forest resource.

2/ International 1/4-inch rule.

PREVIOUS REPORTS ON ILLINOIS' FORESTS

The Forest Survey reports listed below show statistics of Illinois timber production and use. Copies of those reports published by the Central States Forest Experiment Station may be obtained by writing to the Lake States Forest Experiment Station, St. Paul Campus, St. Paul, Minn. 55101.
