Forest Statistics for Mississippi Counties - 1987

Bryan L. Donner and F. Dee Hines

FOREWORD

The Southern Forest Survey, an activity of the Southern Forest Experiment Station Forest Inventory and Analysis work unit, covers the States of Alabama, Arkansas, Louisiana, Mississippi, East Oklahoma, Tennessee, and East Texas, and the territory of Puerto Rico.

This survey is part of the nationwide Forest Survey originally authorized by the McSweeney-McNary Research Act of 1928. More recent legislation pertinent to the survey mission includes the Forest and Rangeland Renewable Resources Planning Act of 1974 and the Forest and Rangeland Renewable Resources Research Act of 1978. The survey mission is to develop, analyze, and maintain renewable forest resource information. This information is essential for formulation of forest policies and programs.

ACKNOWLEDGMENTS

The Southern Station gratefully acknowledges the cooperation and assistance provided by the Mississippi Forestry Commission and forest industries in collecting field data. Appreciation is also expressed for the cooperation of other public agencies and other private landowners in providing access to the sample locations.

Forest Statistics for Mississippi Counties—1987

Bryan L. Donner and F. Dee Hines

INTRODUCTION

The tables and figures in this report were derived from data obtained through a multi-resource inventory of the 82 counties and five survey regions comprising the state of Mississippi (fig. 1). The data on forest acreage and timber volume were secured by a three-step process. First, a forest-nonforest classification was accomplished on aerial photographs for points representing approximately 230 acres. Second, these photo classifications were adjusted on the basis of ground observations at sample locations representing approximately 3,840 acres. Finally, forest locations at the intersections of a grid of lines spaced 3 miles apart were subjected to on-the-ground measurements. At these forest locations, per-acre estimates were obtained from trees measured on a cluster of ten 37.5 basal area factor prism points.

The sampling methods were designed to achieve suitable sampling errors for estimates of area and volume at the state level. Sampling error increases as the area or volume considered decreases. The sampling errors presented in table I, equal to one standard deviation for the sample data, may be used to construct confidence intervals for population parameters. For example, at the 95 percent confidence level, the confidence interval for growing-stock volume (in million cubic feet) in the entire state (with a sampling error of 1.8 percent) is

$$19,425.5 \pm 1.96(0.018 \times 19,425.5) = \\ 19,425.5 \pm 685.3$$

where 1.96 is the number of standard deviations. This confidence interval indicates that the actual growing-stock volume lies in the range 18,740.2 to 20,110.8 million cubic feet, unless a 1 in 20 chance of a random event has occurred. Conversely, the confidence interval for growing-stock volume in a smaller area of consideration, such as Adams County (with a sampling error of 16.4 percent), is 259.9 ± 83.5 or 176.4 to 343.4 million cubic feet.

Sampling errors for any combination of county data in the state may be estimated by using the following procedure:

$$SE_g = \frac{SE_t \sqrt{X_t}}{\sqrt{X_g}}$$

where:

- SE = standard error of estimate
(expressed as a percent)
- X = variable of interest
(area or volume)
- g = total for the group of counties
to be combined
- t = total for the state

For example, the sampling error for growing-stock volume of Choctaw, Noxubee, Oktibbeha, and Winston counties combined is 7.4 percent. Therefore, the confidence interval for growing-stock volume in these four counties is 1152.1 ± 167.1 million cubic feet.

Clarification of three items in the tables and figures is necessary. First, information for several counties in the Delta region was combined in the tables because of the small amount of timberland in those counties. In-

⁴ Tunica included in Quitman.

⁵ Washington included in Sunflower.

formation in the figures, however, was not. Care should therefore be taken when comparing table and figure data for Humphreys, Leflore, Quitman, Sunflower, Tunica, and Washington counties. Second, negative net growth values in table 18 can be attributed to high volumes of certain negative components of the growth equation, such as mortality and cull increment. Third, the unexpected values reported for the hemlock-spruce species group in tables 32 through 36 are represented entirely by Atlantic white-cedar, found in the Gulf Coast area. Atlantic white-cedar is considered a part of the hemlock-spruce species group.

Tables 1-25 were developed to provide compatibility among Forest Inventory and Analysis Projects. Tables 26-36 are supplementary tables and may change from unit to unit or state to state to address specific resource issues.

DEFINITION OF TERMS

Average net annual growth.—Average net annual volume increase for the inter-survey period.

Average annual mortality.—Average annual sound-wood volume of growing-stock trees dying from natural causes.

Average annual removals.—Average net annual volume of growing-stock trees removed from the inventory by harvesting, cultural operations (such as timber-stand improvement), land clearing, or changes in land use.

Commercial species.—Tree species which normally develop into trees suitable for industrial wood products.

Forest type.—A classification of forest land based upon those tree species forming a plurality of live-tree stocking.

Growing-stock trees.—Live trees of commercial species. Rough and rotten trees are excluded.

Growing-stock volume.—The cubic-foot volume of sound wood in growing-stock trees at least 5.0 inches in diameter at breast

height, from a 1-foot stump to a minimum 4.0-inch top diameter outside bark of the central stem, or to the point where the central stem breaks into limbs.

Live trees.—Commercial and noncommercial tree species of sapling size or larger.

Natural stands.—Stands with no evidence of artificial regeneration. This includes those stands established by seed tree regeneration methods.

Noncommercial species.—Tree species of typically small size, poor form, or inferior quality which normally do not develop into trees suitable for industrial wood products.

Planted stands.—Stands with some evidence of planting or direct seeding.

Poletimber trees.—Growing-stock trees at least 5.0 inches in diameter at breast height, but smaller than sawtimber size.

Reserved timberland.—Productive public forest land withdrawn from timber utilization through statute or administrative regulations.

Rotten trees.—Live trees of commercial species that do not contain at least one 12-foot saw log in the butt 16 feet, now or prospectively, primarily because of rot.

Rough trees.—Live trees of commercial species that do not contain at least one 12-foot saw log in the butt 16 feet, now or prospectively, primarily because of roughness or poor form. Also included are all live trees of noncommercial species.

Saplings.—Growing-stock trees at least 1.0 inch but less than 5.0 inches in diameter at breast height.

Sawtimber trees.—Growing-stock trees that contain at least a 12-foot saw log in the butt 16 feet and meet regional specifications for freedom from defect. Softwoods must be at least 9.0 inches in diameter at breast height and hardwoods at least 11.0 inches in diameter at breast height.

Sawtimber volume.—Sound-wood volume of the saw-log portion of growing-stock sawtimber trees in board feet, International 1/4-inch rule, and in cubic feet.

Seedlings.—Growing-stock trees less than 1.0 inch in diameter at breast height and greater than one foot tall for hardwoods, greater than six inches tall for softwoods, and greater than one-half inch in diameter at ground level for longleaf pine.

Site class.—A classification of forest land in terms of inherent capacity to grow crops of industrial wood.

Stand-size class.—A classification of forest land based on the diameter size class of growing-stock trees on the sampled area; that is, sawtimber, poletimber, or sapling and seedling.

Timberland.—Forest land that is producing, or is capable of producing, crops of industrial wood and not withdrawn from timber utilization. Timberland is synonymous with “commercial forest land” in prior reports.

Tree grade.—A classification of the volume of the saw-log portion of sawtimber trees based on the log grade of the butt log.

Woodland.—Forest land incapable of yielding crops of industrial wood because of adverse site conditions.

Figure 26.—Average softwood DBH by county, quadratic mean diameter in inches, two inch diameter classes, Mississippi, 1987. The "0" category indicates no softwood trees were tallied in that county.

Figure 27.—Average hardwood DBH by county, quadratic mean diameter in inches, one inch diameter classes, Mississippi, 1987.

Figure 28.—Average softwood basal area per acre on timberland by county, in square feet, Mississippi, 1987.

Figure 29.—Average hardwood basal area per acre on timberland by county, in square feet, Mississippi, 1987.

Figure 30.—Ratio of average net annual growth to average net annual removals of growing stock for softwoods by county, Mississippi, 1987. A value greater than 1.0 indicates more growth than removals; a value less than 1.0 indicates more removals than growth. The "0" category indicates a county in which not enough information was collected to give meaningful results (See Table 18).

Figure 31.—*Ratio of average net annual growth to average net annual removals of growing stock for hardwoods by county, Mississippi, 1987. A value greater than 1.0 indicates more growth than removals; a value less than 1.0 indicates more removals than growth.*

Donner, Bryan L. and Hines, F. Dee, Forest Statistics for Mississippi counties—1987. Resource Bull. SO- 129 . New Orleans, LA: U.S. Department of Agriculture, Forest Service, Southern Forest Experiment Station; 1987. 79 p.

Tabulates forest resource information from a new inventory of Mississippi counties.

Additional Keywords: Area, volume, forest type, stand size, ownership.
