Table 5.10— A list of 205 plant taxa found by the Science Integration Team to be of particular interest to American Indian tribes within the Basin.

Abies amablis
Abies concolor
Abies grandis
Abies lasiocarpa
Abies spp.
Acer circinatum
Acer glabrum
Agastache occidentalis
Agrostis exarata
Agrostis scabra
Allium acuminatum
Allium douglasii
Allium macrum
Allium madidum
Allium tolmiei
Alnus incana tenuifolia
Alnus spp.
Alopecurus aequalis
Amaranthus graecizans (blitoides)
Amelanchier alnifolia
Ampocynum androsaemi folium
Ampocynum cannabinum
Apocynum androsaemifolium
Apocynum cannabinum
Arctostaphylos nevadensis
Arctostaphylos patula
Arctostaphylos uva-ursi
Artemisia tridentata
Atriplex confertifola
Balsamorhiza careyana
Balsamorhiza hookeri
Balsamorhiza sagitatta
Beckmannia syzigachne
Berberis aquifolium
Berberis nervosa
Betula microphylla
Brodiaea douglassi
Brodiaea howellii
Brodiaea hyacinthina
Calochortus macrocarpus
Cameassia quamash
Carex sp.
Celtis douglasii (occidentalis)
Cercocarpus ledfolius
Chenopodium fremontii
Chrysothamnus bloomeri
Chrysothamnus nauseosus
Cirsium foliosum
Cirsium scariosum
Claytonia lanceolata
Conium maculatom
Cornis stolonifera (pubescens)
Corylus cornuta
Crateagus columbiana
Crateagus douglasii
Daucus pusillus
Descurainia pinnata var. *Filipes*
Descurainia sophia
Elymus canadensis
Elymus cinereus
Equisetum hyemale
Eriogonum umbellatum var. *stellatumi*
Erythronium grandiflorum var. *nudipetalum*
Fragaria vesca
Fragaria virginiana
Fritillaria pudica
Gilia aggregata

Vaccinium parvifolium
Vaccinium scoparium
Valeriana edulis
Veratrum spp.
Wyethia amplexicaulis
Wyethia mollis
Xerophyllum tenax
Zigadenus venenosus

Mature plants with a stout edible stem are referred to as *xamsi*, while other plants with a narrow spindly stem are called *ashwaniya* which means "slave to *xamsi*" (from a story) and are not eaten. These are not, strickly speaking, names for stages of growth; rather, these are individual names for recognizably different plants (Helliwell 1995).

Vascular plant taxonomy is further complicated by local differences in what one tribal group prefers relative to another and also by differences within a taxon across its range. For instance, *Lomatium piperi* and *L. gormanii* are two closely related species often mistaken for one another. However, in central Washington, members of the Yakama Tribe readily distinguish between the two. *L. piperi* is recognized as edible whereas *L. gormanii* is eschewed as "groundhog food." In contrast, in southern Oregon *L. gormanii* is considered quite palatable.[18]

Management of culturally significant plants involves maintaining species viability as well as harvestability and long-term sustained use. For the most part, vascular plants of tribal interest are not rare species. Most are at least locally abundant. One conservation objective may be to ensure that large, healthy, accessible populations will be sustained over the long term.

***Ex Situ* and *In Situ* Conservation of Rare Plants**—*Ex situ* or "off-site" conservation includes a range of activities more or less distinct from *in situ* or "on-site" activities. Off-site and on-site activities often overlap. *Ex situ* activities include seed storage, maintaining living collections in botanical gardens, or various research activities.

[18] Personal communication. 1995. L. Housley, U.S. Department of Interior, Bureau of Land Management, Lakeview Resource Area, P.O. Box 151, Lakeview, Oregon 97630.

Ex situ plant conservation is not an alternative to *in situ* plant conservation, but both are part of a larger, comprehensive conservation effort (McMahan 1990). The Botanic Gardens Conservation Strategy, jointly produced by the World Conservation Union (IUCN), Botanic Garden Conservation International (BGCI: formerly Botanic Garden Conservation Secretariat, or BGCS), and the Worldwide Fund for Nature (WWF), stated: "*In situ* and *ex situ* are the opposite ends of a spectrum and there is no absolute distinction between them." The document goes on to call for a "seamless blend" of *in situ* and *ex situ* conservation as the most effective way to conserve plant species and ecosystems. (Additional information is available in contract reports on file; see appendix 5B for titles.)

Invertebrates

Terrestrial invertebrates are the greatest source of biological diversity within the Basin. Invertebrates are critical components of many ecosystem functions and can make excellent bioindicators of soil and vegetation health. Invertebrates are sensitive indicators of change, and can be used to index changes in the environment at small, spatial and very short, temporal scales.

There are no strictly terrestrial invertebrates that are federally listed as endangered or threatened in the assessment area. One aquatic invertebrate species is listed as threatened and four are listed as endangered (table 5.8). No invertebrates are listed as C1 candidates. Thirty-eight invertebrates (many are aquatic and are not discussed here) are listed as C2 candidates (TS 1995). In the Basin, none of the Forest Service regions lists any terrestrial invertebrate species on their regional sensitive species lists, although individual National Forest lists might vary. The BLM regional offices list 25 (TS 1995). A number of rare or endemic invertebrates exist in the Basin, and some may bear further watching (table 5.11).

Table 5.11— Rare and endemic invertebrate species[1] [L = need attention (potential for listing)[2]; C = currently listed; W = recommended to watch[3]].

[1] These species are currently not listed by any public entity as needing protection. It is the judgment of species or functional group experts that these species be considered for possible measures by federal or state agencies to protect these species.

[2] For reasons specified in the contract reports, these species are thought to need specific attention.

[3] These species are either rare or endemics. There is no information to indicate that special measures are needed at this time to protect them or their habitats; however, because of reasons listed in the contract reports it is prudent to validate their status occasionally. Species with no indicators (L, C or W) are not known to need special protection.

Unique or Representative Habitats

Given the importance of habitat for conservation of invertebrates, unique or representative habitats key to the conservation of the Basin's invertebrate fauna of the assessment area are listed below. These habitats represent a partial list biased toward the taxa investigated in this assessment. Further work will need to address all invertebrates.

- Forested Habitats
  - Montane old conifer forest
  - Old ponderosa pine
  - Oregon white oak woodland
  - Douglas maple
  - Canyon bottom willow swamp
  - Forested/shaded talus
  - Natural riparian woodland in shrub-steppe zone
- Grasslands
  - Mountain meadow
  - Parks in ponderosa pine forest
  - Grassland oak savanna
  - Undisturbed meadow steppe (edge of Cascade Mountains)
  - Undisturbed meadow steppe (Palouse hills)
  - Undisturbed shrub-steppe at pine forest edge
  - Undisturbed shrub-steppe in Columbia River basin
  - Sand dune steppe
- Wetlands
  - Sphagnum bog
  - Low-elevation marshy pond in forest
  - Fen-type bog in Okanagon highlands
  - Hot spring
- Other unforested habitats
  - Alkaline lake shore
  - Cave

Functional Roles of Invertebrates[19]

The following sections discuss groups of invertebrates that perform similar ecological functions. The functions discussed include detritivory and nutrient cycling, wood decomposition, the herbivory functions of snails and slugs, predation, pollination, and grassland and forestland herbivory.

Detritivory and Nutrient Cycling—Contemporary studies indicate that soil resembles a living entity. It "lives" and "breathes" through a complex mix of interacting organisms ranging from viruses and bacteria, fungi, nematodes, and arthropods to ground squirrels, marmots, and badgers. Microbial biomass alone can reach 10,000 kilograms/hectare in productive, inland, western forest soils. Activities of all these organisms are responsible for developing the critical properties that underlie basic soil fertility, health, and productivity. Biologically driven properties resulting from such complex interactions require up to several hundreds of years to develop. No quick fixes are available if extensive damages occur.

Productive ecosystems tend to retain nutrients. Over time, nutrients are metabolized to forms that are less available for plants and animals such as phytates, lignins, tannins, and humic and fulvic acids. For nutrients to once again become available to plants and animals, they must be mineralized by the interaction of decomposers and their predators. These populations and their interactions are important to an ecosystem's stability, including its predator and prey interactions, mutualisms, and diseases.

As total ecosystem productivity increases, biodiversity within the soil food web also increases. The greater number of interactions between decomposers, their predators, and the

[19]Portions of this section rely heavily on information from Harvey and others (1994). Additional information comes from contract reports by Ingham (1995), Frest and Johannes (1995), and Schowalter (1994) (see appendix 5B). Insights on the implications of management practices were gained from information provided by the invertebrate expert panels.

predators of those predators, the fewer the losses of nutrients from that system. In undisturbed ecosystems ("undisturbed" defined hereafter as sites with little disturbance from European settlement) the processes of immobilization and mineralization are tightly coupled to plant growth. Following disturbance, this coupling is lost or reduced; nutrients are no longer retained within the area available to the plants' roots, which reduces the productivity of the ecosystem and causes problems for systems into which nutrients move, especially aquatic portions of landscapes. For this reason, the soil food web has been suggested as a prime indicator of ecosystem health. Measurement of disrupted soil processes; decreased bacterial or fungal activity; inappropriate change in the ratio of fungal to bacterial biomass; decreased number or diversity of protozoa; and altered nematode numbers, nematode community structures, or maturity indices can indicate problems long before the natural vegetation appears to be affected.

Earthworms—A group of invertebrates that play important roles in maintaining soil productivity is the earthworms. Earthworms require organic matter in various stages of decay and in various locations. Three broad functional groups of earthworms have been described by Bouche (1977): epigeic, endogeic, and anecic. Epigeic earthworms reside in leaf litter and under the bark of decaying logs. In a forested site, epigeic earthworms would be expected to have functional roles in organic matter comminution (chewing), in nutrient cycling, in soil structural modification, in the transfer of organic matter to the soil, and as a food source for other animals.

Endogeic earthworms live in the mineral soil and consume organic matter within the soil or at the soil-litter interface. The endogeic earthworm species occur in a wide range of habitats: forest and savannah, grassland and shrubland (including exotic grass pasture and seral stages following cessation of agriculture), and cultivated land. Endogeic species are the least known of all earthworms even though they constitute the majority. Factors that influence populations of endogeic earthworm species in the Basin are unknown. Only by assuming that they are comparable to other earthworms can one say that soil moisture, soil temperature, organic matter quantity and quality, and soil pH are probably the most important factors influencing presence, distribution, and abundance of populations (Lee 1985).

Anecic earthworms are those that inhabit a permanent or semi-permanent deep vertical burrow and emerge at night to consume relatively fresh plant detritus on the surface. Anecic earthworms are unstudied in natural vegetation in the assessment area. Their unique contributions may include the transfer of relatively fresh plant litter from the surface to deep levels of the soil and the creation of deep vertical burrows which assist water infiltration. Anecic species also likely provide food resources to endogeic worms by depositing fecal organic matter into the soil where endogeics can reach it.

The Basin is inhabited by at least three native earthworm species belonging to three genera. *Driloleirus americanus* was considered for inclusion in the IUCN Invertebrate Red Data Book because its habitat was threatened and its range was not known to be very large. Available information suggests that it may be a narrow endemic using a threatened habitat (grassland sites with productive soil). The other two native species, *Drilochaera chenowithensis* and *Argilophilus hammondi*, may be somewhat tolerant of habitat conversion to agricultural uses.

Other Soil Organisms—The other organisms in the soil including bacteria, fungi, protozoa, nematodes, and microarthropods play critical roles in maintaining soil health and fertility (Coleman and others 1992). These roles include: (1) decomposition of plant material by bacteria and fungi; (2) immobilization of nutrients in soil by bacteria and fungi in their biomass and in their secondary metabolites such as waste or defensive products; (3) soil aggregate structure improvement, which increases water-holding capacity, clay surface interactions with nutrients, and plant root architecture; (4) alteration of the soil pH; (5) mineral-

ization of nutrients by protozoan, nematode, and microarthropod predation of bacteria and fungi; and (6) control of disease-causing organisms through competition for resources and space, control of soil micronutrient status, and alteration of root growth.

Wood decomposition—Invertebrates also play key roles in wood decomposition. Secondary bark beetles (also primary, or tree-killing, bark beetles) penetrate the bark of freshly dead trees and inoculate wood with, and provide access to, saprophytic microorganisms. They also provide attractive aerosols, habitats, and resources for other invertebrates such as fungivores and termites, thereby accelerating wood decomposition (Schowalter and others 1992, Stephen and others 1993).

Herbivory functions of snails and slugs—Herbivory functions of snails and slugs help mediate nutrient and energy retention and transfer. Over 150 species of land snails and slugs are found in the Basin. Most are found in moist forest environments and in areas around springs, bogs, and marshes. Basalt and limestone talus slopes are also important habitats for some species.

The land snails and slugs within the Basin are mostly herbivores. A few consume animal matter and some are carnivorous on other land snails. Primary food for the herbivores includes deciduous tree leaves (green and fallen), understory vegetation, large fungi, and inner bark layers. Many mammals, reptiles, amphibians, and some birds prey on land snails and slugs. Various insects prey on snails or parasitize them. Some land snails are intermediate hosts for parasites of vertebrates. Snail shells are used as domiciles, shelters, or egg laying sites for a variety of arthropod taxa.

Taxa Associated with Litter, Coarse Woody Material, and Soil—Most of the invertebrate species associated with litter, coarse woody material, and soil have characteristics that allow them to recolonize disturbed areas and reestablish their functional roles in the ecosystem. Although several species perform the same specific ecological functions, some are less able or unable to survive in disturbed areas.

Frest and Johannes (1995) identified 95 terrestrial mollusks (87 land snails and 8 slugs) as species for which additional conservation attention may be warranted. Areas of high mollusk diversity are concentrated in specific, relatively small portions of the Basin. In particular, many species are confined to calcareous substrates including units such as the Paleozoic Madison, Lodgepole, Mission Canyon, Amsden, Phosphoria, and the Triassic Martin Bridge. Total outcrop areas of these units make up a small part of the total assessment area. Even within the outcrop area of these units, many species, particularly the 95 terrestrial mollusk species of concern, are limited to a small fraction of the total outcrop area. Specific drainages and small geographic areas are particularly significant to mollusk biodiversity. Preeminent areas of mollusk biodiversity are portions of the Columbia Gorge, Hells Canyon, the lower Salmon River, and the Clearwater, Clark Fork, and Bitterroot drainages. For some species, other sites also are very significant, such as a few localities with schist or limestone substrate in western and southeastern Idaho and in western Montana. Similarly significant areas for diversity of land snails are springs in the Upper Klamath Lake drainage, the Columbia Gorge, southeastern Idaho, and specific portions of the Oregon Interior Basins, western Wyoming and the northern quarter of the Basin.

Predation—The terrestrial invertebrate predators within the Basin are a diverse group of arthropods, primarily arachnids and insects that occur in every major habitat. This section covers the spiders (Arachnida:Araneae) and the major insect groups, principally the beetles (Coleoptera), ants (Hymenoptera:Formicidae), social wasps (Hymenoptera:Vespidae) (McIver and others 1994), true bugs (Heteroptera) (Lattin 1995), and lacewings (Neuroptera) (Johnson 1995). Any assessment of such a large, diverse group of species is likely to be superficial for at least two reasons: (1) an assessment even of a group such as the spiders would require information on well over 1,000 species, the majority of which are poorly known, and (2) the available information on each species is widely dispersed and would require an

enormous commitment of time to collect. Hence, this section provides information on the diversity of terrestrial invertebrate predators, their ecological functions, and factors that are thought to affect their abundance and distribution.

A total of 112 families contained in 15 orders and 3 classes of the phylum Arthropoda have species that are predominantly predaceous. Within these families, between 3,540 and 6,640 predaceous species are known to occur in the assessment area. The wide range in this estimate is due to uncertainty because of unknown geographic distributions of many species, incomplete examination of the literature, and incomplete examination of museum records. Although a thorough examination of literature and museum records would improve the accuracy of this estimate considerably, it is beyond the scope of the current project.

Despite the uncertainty of the number of species, arthropod predators clearly occur in great diversity throughout the Basin in every major habitat type. They prey upon virtually every conceivable type of arthropod species. Some major taxa such as the spiders, true bugs and beetles include species that are distributed throughout the Basin, whereas others, particularly the scorpions and pseudoscorpions, tend to occur mostly in dryland and moist microhabitat types, respectively.

In terms of abundance, predaceous spiders and ants dominate the terrestrial arthropod fauna associated with vegetation in the Basin. Beetles, ants and spiders are more prevalent on the ground. Beetles are represented by over 1,300 species, spiders by at least 980 species, and predaceous Hymenoptera by at least 500 species. Other major predaceous arthropod orders are the true bugs (Heteroptera) and the true flies (Diptera).

In managed forest ecosystems, predation is thought to be responsible in large part for regulating arthropod populations including pest populations under endemic conditions (Mason and others 1983). A preliminary evaluation of the HUSSI database (initiated by Hopkins and made available by Torgersen and McKnight, in press) suggests that predation is an ecological process that is a fundamental part of any healthy, natural or managed ecosystem.

Maintaining invertebrate predation processes over the long-term, while maintaining arthropod population fluctuations within some desirable range presents a challenge to managers. In some cases, maintaining predatory function may be as simple as maintaining structures within the landscape that predators are known to require, such as *Camponotus modoc* use of down wood.[20] Down wood, snags, specific habitat features (such as hydrological functions of bogs and springs), forbs, shrubs, and trees of various species and sizes are features to which predaceous arthropods are correlated, much like vertebrates. But unlike the vertebrates, virtually nothing is known about how particular human management practices influence the species composition, abundance, and distribution of predatory arthropods within a given area and the effects of management on ecological function and ecosystem processes. A landscape composed of a balanced mosaic of habitat types will likely have a balanced set of ecological functions.

Arthropod predators and pest insects—Predation has long been regarded as a potent force in suppressing forest insect pest populations. Predators have been implicated as primary suppressive agents of several pest species including *Dendroctonus* species, *Ips* species, pine tip moths, and the two principal defoliator species of western coniferous forests, western spruce budworm (*Choristoneura occidentalis*) (Campbell and others 1983, Torgersen and others 1990) and Douglas-fir tussock moth (*Orgyia pseudotsugata*) (Torgersen and others 1983).

Studies have revealed that birds and ants are primary predators of western spruce budworms (Torgersen and others 1990). In whole-tree exclosure experiments, insectivory predation by several species of passerine birds was identified as the most influential in the upper one-third of the

[20] Personal communication. 1995. Torolf R. Torgersen. USDA Forest Service, Pacific Northwest Research Station, Forestry and Range Sciences Lab, LaGrande, Oregon 97850.

canopy, and predation by ants (primarily) was more effective in the lower one-third. Pupal stocking studies have also implicated thatch ants as causing significant mortality of western spruce budworm. Spiders also might play a role in suppressing budworm populations, particularly when caterpillars are in the earlier stages of development. A key point established by these studies is that a diverse ensemble of predators, including birds, ants, spiders, and other arthropods, prey on western spruce budworm. Management techniques that enhance the role of these predators throughout the budworm population cycle will be likely to pay off in terms of decreased economic loss of green trees. An example illustrating the intricacy of predation effects is the central importance of down wood. Because *Camponotus modoc* nests only in large diameter down wood, maintenance of adequate large-diameter wood will favor larger populations of this important spruce budworm predator. Further, since *Camponotus modoc* is also the primary prey of pileated woodpeckers (*Dryocopus pileatus*), and since these woodpeckers excavate cavities used by a variety of insectivorous birds, management of down wood can provide substantial benefit by encouraging the maintenance of larger populations of budworm predators, principally ants and birds.[21]

Many studies involving stocking experiments (for example, Mason and Paul 1988) and key-factor analysis (for example, Mason and Torgersen 1987) have implicated predation as a primary cause of declines in Douglas-fir tussock moth populations. Primary predators that contribute to mortality include the jumping spider (*Metaphidippus aeneolus*), philodromid hunting spiders, web-spinning spiders, heteropteran predators, predaceous ants, and birds (for example, Mason and Paul 1988). Although predation may contribute well over one-half of the total mortality of tussock moth larvae and pupae during outbreak conditions, even this level of suppression might be inadequate to deflect the outbreak population trajectory (Mason and Wickman 1988). Hence, predation is typically thought to be most influential on tussock moth populations during non-outbreak (or endemic) phases of the moth's population cycle. Management activities that increase the rate of predation during these endemic conditions are, therefore, most likely to either defer or decrease subsequent population levels during the outbreak phase.

The HUSSI database also helped us identify some of the major predators of several insect pest species including pine tip moths, tussock moths, budworms, sawflies, tent caterpillars, and bark beetles. A total of 71 predator species have been observed to attack these pest insect species, 33 for *Dendroctonus* species alone. These numbers are likely underestimates of the actual number of predators that attack pest insects.

Additional attention may be warranted for 13 species of arthropod predators, including eight beetles and five bugs. Other species likely warrant attention but our knowledge of them is inadequate to either identify them or document their scarcity or sensitivity to disturbance. In addition, McIver and others (1994) provided additional detailed information on 14 other "exemplar" species that were chosen to represent the taxonomic diversity and ecological functions of invertebrate predators. These exemplar species include five species of beetles, two species of ants, one species of social wasp, and six species of spiders.

Critical Factors Affecting Arthropod Predators—Probably the only way to manage most arthropod species effectively is to manage their habitat. Among inherent environmental features, the architecture of the physical environment upon which predators depend for hunting and nesting is of primary importance. Plant architecture (that is, size, number, and arrangement of leaves, needles, and branches) is known to influence presence of canopy spiders (for example, Gunnarsson 1988). Plant species composition has been shown to influence abundance of spiders as well. Physical structures, such as down logs, can provide nesting, foraging, or hiding habitat for major predator species such as ants (including *Formica* spp. and *Camponotus modoc*),[22] beetles, and spiders. Many

[21]See footnote 20.

[22]See footnote 20.

predator species are associated with specific habitat types suggesting that special attention be paid to management of these features.

The second category of factors that can influence conservation of arthropod predators is disturbance. In the most basic sense, any disturbance that affects habitat will affect the species that depend on that habitat. For example, short fire-return intervals in cheatgrass-dominated rangelands in southern Idaho will very likely eliminate dominant predator species such as the thatch ant, *Formica obscuripes*. Thatch ants have the following ecological functions. Thatch ant nests provide habitat for over 100 species of other arthropods, serve as overwintering and foraging habitats for small mammals, and concentrate nutrients on a local scale. In addition, thatch ant workers care for several species of aphids and other Homoptera, are predators and scavengers of other insects, and the workers and pupae are prey for other vertebrate insectivores. Where they occur, thatch ants are probably responsible for the majority of secondary production through conversion of honeydew and prey proteins into ant protein. Although thatch ant colonies can survive fire by maintaining the queen and brood below ground, post-fire survival is challenged by a lack of resources since the sagebrush-feeding Homoptera that the ants depend on for honeydew energy are typically eliminated. Hence, thatch ant colonies are generally reduced by fire to less than 20 percent of their original size. Fire events every few years will likely drive these challenged colonies to extinction.

A general trend in the northern Great Basin is the removal of sagebrush and other shrubs upon which Homoptera feed and the subsequent loss of the thatch ant. Vegetation communities and ecosystems with short fire-return intervals (typically cheatgrass-dominated) will tend to favor "weedy" ant species with different ecological functions. In general, because many of our ecosystems have been modified significantly by fire suppression, grazing, and the introduction of exotic plant species, use of prescribed burning may not meet the objective of returning the land to its previous condition. Hence, it is suggested that prescribed burning be used with caution and with native species in mind.

Forest silvicultural practices can have profound effects on the composition of predator species in a given area. In coniferous forests of western Oregon, clearcutting causes a complete replacement of forest-dwelling, litter spiders with species that are adapted to sunny, open places (McIver and others 1992). Selective cutting, the more typical silvicultural practice in eastside forests, is not likely to have such an effect, but more work needs to be done to determine the connection between silviculture, predator species composition, and the benefits that predatory species provide to the ecosystem. Structural diversity, including varying ages of conifers, angiosperms, and standing and down dead wood, are important components in maintaining the microhabitats, moisture regimes, light regimes, food plants, and prey base for arthropod predators.

Several species of tiger beetles (Cicindelidae: Coleoptera) occur as top invertebrate predators in sand dune steppe habitats along the Snake, Salmon, and other rivers of Idaho. The tiger beetles are threatened by recreation (especially off-road vehicle use), grazing and trampling by livestock in a few places, and dune stabilization efforts (including removal of exotic grasses and change of dune vegetation structure). The Idaho State Office of BLM has developed a Habitat Conservation Assessment and Conservation Strategy for these species.[23]

Pollination—About 67 percent of all flowering plant species benefit from insects that visit their flowers (Axelrod 1960). In the absence of insect pollinators, these plants would reproduce at substantially lower rates or not at all. Bees (Hymenoptera), butterflies and moths (Lepidoptera), flies (Diptera), and some beetles (Coleoptera) are the main insect taxa that visit flowers.

[23]Personal communication. 1995. Allan E. Thomas, Fish and Wildlife Biologist. U.S. Department of Interior, Bureau of Land Management, Idaho State Office, 3380 Americana Terrace, Boise, Idaho 83706.

The primary insect pollinators of plants in the Basin are native bees. Bees are the only organisms, with a few minor exceptions, that depend exclusively on pollen and nectar for food throughout their lives. Among flower visitors, bees are the most reliable and efficient group at transferring pollen among flowers. The most obvious exception is at higher elevations where flies assume increased importance (del Moral and Standley 1979) apparently because of their greater ability to cope with high altitudes and cold temperatures.

Based on 8,350 specimen records documented in unpublished and published reports on file at the Bee Laboratory in Logan, Utah, 647 species of bees are presently known to occur in the Basin. However, the actual number of bee species in the Basin is believed to be substantially higher because little collecting has been conducted in this region. Based on other areas in the western United States that have been sampled more extensively, Tepedino and Griswold (1995) estimated that the actual number of bee species in the Basin is much closer to 1,000. Little biological or ecological information is known about most of these species.

The primary ecological function of native bees is as pollinators of flowering plants. Without bee-facilitated pollination, few if any seeds or fruits would be produced by these plants. In addition, bees can influence the genetic variability of the seeds produced by the plants that they visit; they can affect the rate of inbreeding in plants with self-compatible flowers by their movement patterns within and between plants. The products of pollination, fruits and seeds, are important not only to the plants that produce them but also to the numerous birds, mammals, and insects that use them as food for all or part of the year.

Many bee species are specialized to some degree and collect pollen from a restricted group of plants. The degree of specialization on plants ranges from fairly broad groups of plants (such as pollinating composites) to only particular plant genera. Generalist bees (such as Halictinae and Bombinae), visit a variety of flowers on individual foraging trips.

Ground-nesting bees, particularly those that breed in large aggregations of thousands of nests, move large amounts of soil while digging their main burrows and side branches. In so doing, they help to recycle soil layers and nutrients.

Grassland herbivory—In grasslands, several invertebrate groups function primarily as grazers and are important links in food webs. Most invertebrate herbivores that inhabit grasslands feed on various herbs, shrubs, and trees and they are seldom considered pests. However, some taxa, such as some species of grasshoppers, are of economic importance when populations reach outbreak levels and consume significant amounts of vegetation. In addition to being important consumers of vegetation (annual primary production), grassland herbivores provide important food resources for a wide variety of wildlife and are an especially critical resource for nesting birds and their broods in the spring.

Many arthropod species function as grassland herbivores. Three groups of grassland herbivore species will be considered in this section: grasshoppers (Acrididae; see also Kemp 1994), moths and butterflies (Lepidoptera; see also Hammond 1995), and true bugs (Hemiptera:Heteroptera; see also Lattin 1995).

Approximately 100 species of grasshoppers inhabit the grasslands of the assessment area. Most populations fluctuate in numbers in direct response to available food resources. Unfortunately, we know much more about how to control populations of grasshoppers in grasslands than we do about the specific ecological roles of these species. Furthermore, what little we do know about the ecology of grassland grasshoppers comes from grasslands other than (and in a number of cases very different from) those within the Basin.

Recently, considerable progress has been made in understanding the rich species diversity of moths and butterflies (Lepidoptera) within western coniferous forest ecosystems. Parsons and others (1991) reported 492 species of moths and butterflies collected from the H.J. Andrews Experimen-

tal Forest in western Oregon. Similarly, Grimble and others (1993) found 438 species of moths and butterflies on the Umatilla and Wallowa-Whitman National Forests in eastern Oregon. In both of these areas, 90 percent of the species feed on angiosperms and only 10 percent use conifers as a food source. Less is known about the diversity of moths and butterflies in western grasslands, but 302 species have been recorded from the semi-desert grasslands of Harney County in southeastern Oregon.

About 307 species, 163 genera, and 30 families of true bugs occur in the assessment area.[24] We have reasonable knowledge of the general biogeographical distribution of the true bug fauna of the region based on collections at Oregon State University, Washington State University, the University of Idaho, the University of British Columbia, and the California Academy of Sciences and from the personal experiences and reprint library of J.D. Lattin, Oregon State University.

All of the grassland herbivores discussed above act as primary plant consumers; however, their degree of plant specificity varies between groups. Most butterflies feed exclusively upon a single type of plant. Grasshoppers display varying degrees of host plant specificity. However, the grasshopper species that frequently occur in high densities and that are detrimental to agricultural production are generalists that graze on a variety of grasses, forbs, and cereals. For true bugs, host specificity depends on the bug group and the plant group involved. Bug species that feed on grasses tend to have lower host specificity than those that feed on trees.

Herbivory by insects can influence the rates of nutrient cycling of elements such as nitrogen and carbon. This function is of particular significance with pest species that consume large amounts of vegetation (for example, generalist grasshoppers in various range habitats and *Labops hesperius* in fields of crested wheatgrass).

[24] Personal communication. 1995. J. Lattin, Oregon State University. Corvallis, Oregon 97331. Personal communication of unpublished data.

Small vertebrates such as some passerine birds, rodents, shrews, and bats, are dependent on insects for a protein source when rearing their young in spring and early summer. For example, the nesting success of western sage grouse is tied to their dietary needs, primarily succulent forbs and insects. These primary predators then become food for secondary predators such as hawks, owls, coyotes, and bobcats.

Forest Herbivory—Several groups of invertebrates feed either as immatures or as adults on the forbs, shrubs, and trees of forests. In addition to being primary consumers, which are in turn eaten by various invertebrate and vertebrate predators, they directly or indirectly influence forest ecosystem processes in a variety of ways.

Forest herbivore insects have traditionally been viewed as pests that interfere with management objectives by damaging forest resources. Thus, management concerns and research emphases have concentrated on single species, principally tree defoliators and bark beetles, and only during high population densities (Huffaker and others 1984). This work has been successful in providing information on how these organisms affect other parts of the ecosystem, including forest succession, and has helped to identify the necessary tools for their control.

Within the current assessment, two other efforts have examined aspects of invertebrate forest herbivory. Hessburg and others (1995; see also Landscape Dynamics chapter, this document) assessed landscape susceptibility to major defoliator and bark beetle disturbance, and Kurtz and others (1994) modeled the role that specific bark beetle and defoliator species play in forest succession. While we address these topics in this chapter, we also refer the reader to these sources for more detailed assessments.

The taxonomic groups addressed in this section are moths and butterflies (Lepidoptera), bark beetles (Coleoptera:Scolytidae) and their associated mites (Acariformes), true bugs (Hemiptera: Heteroptera), sawflies (Diprionidae and

Tenthredinidae), and aphids (Aphiodidae). See Hammond (1995), Miller (1994), Ross (1995), Moser (1994), and Wagner and McMillin (1994) for further information about these forest herbivores.

All invertebrate forest herbivores have the potential to influence forest ecosystem processes and interactions in many ways by changing the following: (1) microclimate and water relations, (2) carbon and nutrient cycling or energy flow through the ecosystem, (3) plant succession or community structure, (4) food sources for other organisms, (5) wildlife habitat, and (6) pollination of plants in the forest ecosystem (Haack and Byler 1993, Schowalter 1993). The following discussion provides examples of such effects.

Reductions in percent tree-canopy cover or tree basal area in a forest stand from insect-caused defoliation or tree mortality can, in turn, influence interception of precipitation, evapotranspiration, light penetration, and wind speed (Speight and Wainhouse 1989). In addition, tree defoliation or tree mortality temporarily removes actively transpiring foliage from the forest canopy. This reduces the flow of water from the root zone to the tree canopy and therefore can lead to increased soil moisture. Warmer soil temperatures in the spring and summer in combination with increased soil moisture caused by defoliation by insects provide a generally more favorable microclimate for invertebrate activity. Therefore, environmental conditions may become more favorable for decomposition of organic matter in defoliated stands than in non-defoliated stands (Klock and Wickman 1978), especially during dry periods (Schowalter and Sabin 1991). Furthermore, the improved water balance as a result of decreased transpiration may enhance plant survival during drought periods in some environments (Schowalter 1993).

The importance of arthropods in contributing to biomass decomposition, carbon cycling, nutrient cycling, soil fertility, and energy flow in forest ecosystems has been recognized for several years. Forest invertebrate herbivory contributes to both short- and long-term nutrient cycling processes in forest ecosystems. Low levels of defoliation (for example, less than 7%) can return as much as 30 percent of foliage standing crop of potassium and 300 percent of foliage standing crop of sodium to the litter than would otherwise occur (Schowalter and others 1986). In addition, a considerable amount of mobile elements are returned indirectly to the soil by defoliation as a result of increased leaching from damaged foliage during rainfall. Insect remains and grass also contribute to litter and may decompose faster than do fallen leaves and needles. This may result in faster cycling of elements such as calcium, potassium, nitrogen, and phosphorus.

An additional role that herbivorous insects play in the forest ecosystem is as pruning or thinning agents which may stimulate plant growth and increase biomass turnover (for example, Velaquez-Martinez and others 1992). Pruning and thinning of plant parts can help stimulate plant growth by reducing competition for limited light. Although insects and pathogens typically remove less than 10 percent of foliage and shoots in non-outbreak years, removal of these plant parts apparently reduces plant metabolic demands and facilitates reallocation of plant resources.

Hard data are not available to indicate the importance of these insect-mediated effects on nutrient cycling and the long-term productivity of forest ecosystems. However, growth responses of trees to the addition of nutrients, in general, will occur only when growth at that site is nutrient-limited (Speight and Wainhouse 1989).

Tree growth and mortality is affected by insects and diseases, as they in turn influence microclimate, water relations, nutrient and carbon cycling, and direct loss of foliage. These effects on individual trees are ultimately manifested as changes in stand and ecosystem structure and function (Schowalter and others 1986). Selective herbivory by insects can favor tree species resulting in changes in stand age, plant composition, and tree density.

Trees killed by insects are used as wildlife habitat both as standing snags and down wood. In areas where cover is plentiful but forage is limited, severe defoliation caused by insects can have a positive influence on deer and elk use by increasing the amount of forage biomass within two to four years (Thomas 1979).

Forest herbivores are preyed upon by a variety of other arthropods and vertebrates. Arthropod predators of defoliators include spiders, ants, true bugs, nerve-winged insects, beetles, flies, and wasps. Of animals other than arthropods, birds probably consume the highest number of tree-feeding insects. There are at least 32 species of birds that feed on the western spruce budworm and Douglas-fir tussock moth in eastern Oregon and Washington ecosystems. In one study, mountain chickadee (*Parus gambeli*) and red-breasted nuthatch (*Sitta canadensis*) were the most common predator of western spruce budworm and Douglas-fir tussock moth (Torgersen 1994).

Butterflies are an example of a forest herbivore group that would make a good indicator of total ecosystem diversity (Hammond 1994). They are relatively conspicuous and easy to observe in the field, and their functional role is well known. Their abundance and diversity relates directly to the presence of their host plants as they are generally monophagous. Butterflies, in turn, support a rich diversity of generalist predators including arthropod predators and parasites, passerine birds, bats, rodents, and other small mammals. Other invertebrate herbivore groups may offer similar opportunities to act as indexes to important ecosystem functions or to total ecosystem diversity.

Implications of Management Practices on Invertebrates

Little information exists on the effects of management practices on invertebrates because the importance of the ecological functions performed by these organisms has not been recognized previously. In this section we discuss some general principles which may be used to help conserve invertebrates. After that we discuss some implications of management practices on various invertebrates including those associated with detritivory and nutrient cycling, anthropod predators, bees, grassland herbivores, and forest herbivores.

Three guiding principles may help to conserve invertebrates: (1) provision of a diversity of habitat composition and structures to maintain invertebrate biodiversity and ecosystem functions, (2) maintenance of soil structure and chemistry to sustain diversity and functions of the invertebrate food web in the soil, (3) eradication or prevention of the introduction of exotic organisms to maintain invertebrate biodiversity and ecosystem functions.

Habitat composition and structures—Alteration of the structure of the forest canopy layer from tree harvest, tree stand improvement activities, or wildfire, affects several functional groups of invertebrates. The altered forest stand may be more or less hospitable to various herbivores resulting in different amounts of nutrients in foliage falling to the litter or different rates of subsequent tree mortality. The changes may result in varying quality and quantity of prey available to predators including both invertebrate and vertebrate species. Changes in density or composition of the tree canopy can affect habitat for predators that help control population irruptions of pest species. Also, canopy changes cause microclimatic changes in the understory, and in coarse woody material and litter environments which may be detrimental for some species. For example, if the light/moisture regime is changed sufficiently, the understory angiosperm flora may change, resulting in affects upon pollinators, herbivores, and predators. These changes in forest stand structure may be inimical to species such as land snails whose lack of mobility may prevent them from seeking conditions in disjunct patches of forest habitat. In addition, coarse woody material may dry out more quickly, thereby affecting the internal environment within standing and down dead trees and altering suitability for decaying-wood dwelling invertebrates.

In the forest understory, management practices that disturb flowering plants and other ground vegetation or that compact or mix the soil may have distinct effects on several functional groups of organisms. In addition to the effects of management practices on organisms with limited dispersal capabilities or those that are in a non-mobile stage, habitat of many functional groups of invertebrates can be disrupted. Consequently plant and animal communities can change, sometimes resulting in detrimental effects to particular invertebrate species.

On the forest floor, the major structural element contributing to the invertebrate fauna is coarse woody material. This consists primarily of down tree boles and large branches. This material serves as habitat for prey for mammalian, avian, and invertebrate predators and as a carbon source for soil biota. Various species of arthropods, nematodes, fungi, annelids, and bacteria are responsible for the comminution and conversion of the wood to elements that are available to the soil. To maintain soil productivity, sufficient coarse woody material should be maintained through time. In grasslands, retaining native plant species is important as they may be key to maintaining large invertebrate communities of over 100 species representing several functional groups.

Soil structure and soil chemistry—Maintenance of forest soil chemistry and structure helps to sustain soil health and fertility. This is vital to retaining forest and range productivity and biodiversity. Chemical changes of soil from fire and structural changes of soil from compaction or mixing of soil layers are two results of management practices that are of concern. Fire, whether natural or human-caused, has the potential to consume the litter and coarse woody material that are the primary sources of carbon and other elements necessary for the soil food web. Erosion, resulting from loss of soil-binding materials, further depletes the capacity of the soil. Fire can volatilize nutrients found in the upper horizon of the soil and change water-retention characteristics. Structural changes to soil from either compaction or soil mixing can have long-lasting effects on successional patterns and duration. These effects are expected with multiple management entries into a forested area.

Exotic Organisms—The introduction or maintenance of exotic invertebrates and plants can adversely affect range and forest succession and reduce native invertebrate diversity. Sailer (1983) and Kim and McPheron (1993) reported that nearly 2,000 species of exotic insects and mites have become established in North America. Mattson and others (1994) listed all of the immigrant phytophagous (plant-eating) insect species known to have become established in North America on native and introduced woody plants (that is, trees and shrubs). More than 368 species of exotic phytophagous insects have become established in North American (north of Mexico) forests, parks, woodlots, shelterbelts, and orchards. The orders Homoptera, Coleoptera, Lepidoptera, and Hymenoptera account for most of the introductions. The majority of the species have come from the western Palearctic (Old World) and Asia.

Without their native enemies to restrain population growth, exotic organisms can occupy the niches of native species. The exotic species, because of their competitive nature, may become pests and may require eradication or suppression activities and concomitant risks and financial costs.

Implications for Invertebrates Associated with Detritivory and Nutrient Cycling—Groups of viruses, bacteria, protozoa, rotifers, nematods, microfungi, and algae, all help determine productivity of many parts of the ecosystem, especially soils, organic matter decomposition, and other aspects of the below-ground environment. Most are critical to maintaining diverse ecosystems and productive and sustainable renewable resources. In particular, knowledge of how land management activities affect various kinds of soil bacteria is important because some (desirable) bacteria species inhibit disease-causing organisms, whereas other (undesirable) bacteria species will cause disease.

Two areas of concern for invertebrates are the direct effects of fire on populations and the role of fire in forest or range succession and soil chemistry. In fire-adapted systems, direct effects on invertebrate populations are thought to be slight. However, in systems where large volumes of fuel (litter and coarse woody material) are present, higher intensity fires may pose hazards to slow-moving organisms such as land snails. Direct effects on invertebrates will be reduced if refugia of litter and coarse woody material are retained.

Fire removal of organic matter has opposite effects on forest and range succession. In the forest, loss of organic matter may change the ratio of fungi:bacteria to favor bacteria. This change in ratio favors grasses rather than woody vegetation, not necessarily the direction desirable in forestry. In grasslands, the consumption of organic matter and the subsequent change to a bacteria-dominated food web is beneficial to the maintenance of grasses. The effects on invertebrates by early-season fires in cheatgrass with its damage to native perennial grasses is unknown.

Coarse woody material provides habitat for prey of other organisms, serves as primary habitat for invertebrate predators, and serves as a carbon source for the soil food web. It is not known how much litter and coarse woody material and what sizes are necessary to continue ecosystem functions of associated invertebrates. It is assumed that the standards to provide prey for vertebrate species will suffice to continue the functions of invertebrate populations.

Compaction or mixing of soils is an issue that has implications for maintaining the soil food web. Compaction occurs from use of machinery on the land and from the effects of grazing by large herbivores. Compaction reduces soil pore size which results in loss of nutrient retention and increases the bacterial component of the soil-based food web. This may reverse succession in the forested environment, causing a negative impact on cyanobacteria, lichen, and mat-forming ectomycorrhizal fungi. With loss of the ectomycorrhizal fungi, tree productivity declines. Compaction also changes the community of nematodes, favoring bacteria and root-feeding species. Root-feeding nematodes can be highly detrimental to survival of tree and grass seedlings.

Compaction has a negative effect on all other groups of invertebrates but especially mollusks and earthworms, which may occupy specific habitats or which cannot disperse quickly. Overgrazing and the congregating of livestock near water sources can directly affect mollusks by trampling individuals and degrading their favored riparian habitats.

Tilling to reduce compaction and other means of physically mixing the duff and soil can potentially adversely affect many ecological functional groups of invertebrates. Disruption of the duff/litter layer has immediate effects on water and thermal relations, degrades habitat for many functional species groups that inhabit woody debris and litter, and alters forb and flowering plant communities. Excess mixing of soils affects the soil food web by breaking roots and fungal mats and by changing water and thermal conditions, thereby encouraging growth of bacteria populations.

The use of pesticides mostly negatively impacts mollusks. Further consideration should be made to determine the non-target effects on mollusks of using pesticides.

Implications for Arthropod Predators—The following practices may help to ensure the health of habitat-specific, forest predator populations: (1) cautious management of low elevation, old forests because they represent such a low percentage of habitat types and since the microhabitats they provide are favored by a number of predaceous species, (2) management of other forests to include retention of legacies of its former character so that there are source areas from which plants and animals may colonize the disturbed areas, (3) provision of uncut forest buffer zones for bogs and wetlands including lake-edge and stream-edge grasslands, and (4) maintenance of an uncut forest buffer zone around sand, gravel, canyon, waterfall, spring, and cave habitats because these habitats harbor unique predator species.

Overgrazing of shrub-steppe, prairie, savannah, or mountain meadows can eliminate arthropod predator species through conversion of perennial grasses to introduced annuals. Range managers could strive to maintain native plant populations as these habitats favor native arthropod predator species.

Recreation activities potentially damage arthropod predator habitat by trampling areas or by associated development of roads and facilities. Caves are probably the most critical habitat that is affected by recreation. Some of the more unusual arthropod fauna live within these caves. Excessive and uncontrolled use of caves by recreationists can cause habitat degradation in numerous ways.

Wildlife can, in some cases, damage important habitat. For instance, sphagnum bogs can become flooded by beavers. Where bogs are to be preserved, beaver removal could be considered. Exotic plants or arthropods that are introduced as biological controls of pest species may competitively displace native species that are important to beneficial predators or other functional groups.

Implications for Bees—Four major implications of management practices on bees pertain to effects on nesting habitat, flowering plant resources, exotic flora and fauna, and use of pesticides.

The nest sites of ground-nesting bees may be subject to a variety of disturbances. Land use activities such as grazing, mechanized activities, off-road vehicle use, and subsoiling can damage maturing progeny in the soil and disrupt current nesting activity. Sites in vertical or near-vertical embankments are subject to erosion, whereas sites in more level ground are vulnerable to compaction. Effects caused by constant or heavy use can vary greatly by site. Some degree of compaction on heavier soils may be tolerable and even beneficial to certain ground-nesting bee species. However, bees that inhabit light soils, particularly sandy soils, occur in higher densities and include more endemic species than in other types of soils, and are extremely sensitive to disturbance. Activities can also obliterate or change the subtle landmarks adjacent to nest-holes that bees use to find their nests when returning from foraging trips. Disturbance early or late in the year when bees and most plants are less active would reduce effects. In addition to seasonal mitigation, any reduction in the intensity and frequency of such disturbing activities will help to maintain adequate ground-nesting habitat and provide time for recovery and recolonization of sites.

Habitat availability for wood-nesting bee species can be adversely affected by any management practices that remove wood resources (such as, prescribed burning, intensive tree harvesting, and intensive vegetation management). Many of these practices can open up forest habitat for foraging and breeding by ground-nesting bees by increasing light penetration, and thus increasing flowering plant abundance. On rangeland and in open forests, fire occurring during active bee nesting and foraging seasons results in direct mortality of bees and decreases habitat for wood-nesters. Since closed forests have no significant use by bees, seasonality of fire is inconsequential; but seasonality of fire is of consequence in rangeland and open forests.

The easiest and most straightforward way to manage for bees of all degrees of specialization is to maintain or augment the diversity of flowering plant species. Carefully managing domestic grazing practices on public lands can help promote native plant diversity and, therefore, bee diversity in the assessment area. Careful rotations and exclusions of selected rangelands might enhance plant and bee diversity particularly in higher elevation and forested sites. Where annual grasses predominate, such as in many grazed areas, pollinators are reduced in numbers as a result of resource depletion. Any activity that reduces cheatgrass or other introduced annual grasses will likely benefit the diversity of native flowering plants and the abundance of pollinators. Grazing by sheep has a particularly strong effect on flowering plant diversity as sheep are forb eaters.

Herbicides are the most obvious immediate detriment to floristic diversity. Current management policies that limit the use of herbicides to spot applications can help maintain plant and bee diversity, whereas broad-scale use can reduce diversity of angiosperm and associated bee species.

Where plants with specialist bees are known to occur, grazing, burning, and other activities with similar effects on the flora can be timed to periods when these plants are not flowering. Silvicultural practices that leave clusters of trees are preferred methods as they will result in an increase in floral diversity while maintaining other habitat requirements.

Management activities aimed at providing for the bee fauna could encourage a move away from exotic plants such as crested wheatgrass, Russian forage kosha, and cheatgrass, and toward native plant species. Both the promotion of current exotics and the introduction of new exotic species could be discouraged. The intentional introduction of either non-native or native bees into areas they did not originally occupy to pollinate agricultural crops as well as accidental introductions could result in the competitive displacement of native bee species.

Chemical insecticides currently being used on grasshoppers are highly toxic to bees. Use of insecticides is currently restricted on Federal lands in the assessment area to controlling grasshoppers on rangelands adjacent to agricultural areas. While situations will always exist where insecticides are the only recourse, the judicious use of them may help to minimize adverse effects on bee diversity and abundance. Alternative control methods could be implemented whenever possible. When insecticide spraying is the only treatment available, unsprayed strips could be left to help retain beneficial fauna, and applications could be made on different tracts of land each year. Carbaryl baits are the preferred treatment for grasshoppers because such baits have a lower effect on leafcutter bees than do spray applications.

Implications for Grassland Herbivores— Three major issues related to managing grasslands for insect herbivores are the effects of management activities on plant community composition, the introduction of exotic flora and fauna, and the effects of insecticides.

Changes in plant community composition affect the herbivore community by changing the availability of their host plants and the abundance of generalist predators. Management activities that change vegetation structure, vegetation biomass, and plant species composition can affect presence and densities of insect herbivores in grasslands. A diverse insect fauna is best ensured by maintaining a structurally and taxonomically diverse floral community.

Season-long grazing tends to convert grassland plant communities to earlier seral stages that have increased likelihood of invasion by exotic species. Such conditions increase the probability of a less diverse grasshopper community that could easily be dominated by one of the generalist pest species. Season-long grazing also reduces the diversity of moths and butterflies in most areas because of the loss of food plants for larvae. Grassland vegetation structure and plant species composition can be manipulated to increase species diversity of grassland herbivores and to reduce the likelihood of irruptions of individual pest species. The intensity, duration, season, and spatial extent of grazing regimes are all factors that potentially can be restructured to favorably alter plant communities. Grazing can be used as a tool to maintain or restore diversity of grassland herbivores, if done carefully.

Fire has little direct effect on insect populations unless burns are timed to kill all individuals that would emerge that season. A greater effect is the way fire can shift plant community composition. If burning, especially in association with other disturbances, results in areas that are dominated by early successional forbs, outbreaks of some herbivorous invertebrate species may occur, at least in the short-term. A "cool" fire may have positive effects on moths and butterflies by opening up the

community to their preferred food plants. A "hot" fire could result in mortality of shallow-rooted plants which could decrease diversity of closely associated herbivores.

The second issue related to management for grassland herbivores is the invasion of exotic flora and fauna. Unfortunately, most native insects, with the exception of a few grasshopper species, are unable to feed on exotic plant species. The result is a reduction in the diversity of grassland insects, including predaceous as well as herbivorous species, leading to the specific favoring of one or a few insect species of the community. An example is the favoring of various species of grasshoppers, such as *Irbisia pacifica* and *Labops hesperius* in crested wheatgrass, and *Lygus* spp. in kochia.

The consequences of proposed introductions of exotic enemies (for example, scelionid egg parasites and fungal pathogens) to control native grasshoppers are unclear. Such actions may disrupt natural interactions in unanticipated ways. The effect of introducing exotic control agents on native biological control agents is largely unknown. Since only a small proportion of grasshopper species are pests, such practices could put non-target species at risk. Introduction of exotic control agents only after possible direct and indirect effects have been rigorously assessed would help maintain native control agents.

The third issue related to management for grassland herbivores is the role of insecticides. Broad spectrum insecticides, like malathion and carbaryl, can produce drastic reductions in both community composition and densities of grassland grasshoppers. Furthermore, populations of many non-target species often are affected negatively, including moths and butterflies, bees, beetles, and aphids. Bait applications of carbaryl are less harmful to flying, non-target insects than they are to non-flying insects, but may negatively affect ants. Many other arthropods that may be affected by spraying insecticides are predators of grasshoppers that provide a natural control. Once they are eliminated, acute problems may turn into chronic problems. Insecticides also may have secondary negative effects on insectivorous birds if most of the prey base is killed.

Implications for Forest Herbivores—Major issues related to forest herbivores include the effects of management on overstory and understory host plant availability. Management activities affect canopy and bole herbivores indirectly by altering their food source. Tree species composition, tree age and size, stand structure, and stand stress, influence the composition and relative abundance of forest invertebrate herbivores.

Forest management practices affect understory herbivores in several ways: (1) indirectly by altering the density of the overstory canopy which in turn influences the type and abundance of understory plants, (2) indirectly by manipulating the understory vegetation, and (3) by direct mortality caused by application of pesticides for overstory defoliators. Changes in the assemblage of understory herbivore species can affect plant community dynamics and the predators and parasites that use these species as prey or hosts.

Vertebrates

Vertebrate species occupy widely diverse habitats in the Basin and play various ecological roles. Five hundred forty-seven terrestrial vertebrate species were evaluated for this assessment, 47 of which are listed under the Endangered Species Act as endangered, threatened, or Category 2 candidates (C2). This section presents a summary of findings listed by vertebrate taxonomic class. Additional species information and databases with information on cover types and structures, environmental correlates, and ecological functions are on file (TS 1995).

Amphibians

Information on the distribution and abundance of amphibians in the Basin is quite limited. They are difficult to survey because localized populations may fluctuate widely over time and trends are difficult to determine. Distribution and abundance of many amphibian species are more closely associated with specific substrates (such as down wood) and microhabitat conditions (such as deep,

moist talus), than with general vegetation cover types and structural stages. Most amphibian species require water, either standing (including wet meadows, marshes, and ephemeral ponds) or flowing, for egg laying and larval development. A few species, such as the Larch Mountain salamander (*Plethodon larselli*), may lay eggs in moist habitats but are associated with down wood or talus as adults rather than aquatic environments. Frogs are primarily inhabitants of forested vegetation but some occur in shrub or grasslands. Riparian habitat is important for most adult forms. Dispersal occurs both in water along streams and within 400 meters of the stream.

Exotic species, such as bullfrogs and some fish introduced into high elevation lakes have been detrimental to many amphibian species. In some cases, these introductions may be responsible for the decline or elimination of species, such as the northern leopard frog (*Rana pipiens*), from some locations (Leonard and others 1993).

A number of amphibian species have declined or disappeared from portions of their ranges from undetermined factors or a combination of factors. These species include the southern race of the Columbian spotted frog[25] (*Rana luteiventris*), northern leopard frog (*Rana pipiens*), and western toad (*Bufo boreas*).

Key ecological functions provided by amphibians includes the storage and transfer of energy and nutrients from aquatic to terrestrial systems. Most species, especially the larval stages, provide high biomass in aquatic and some mesic terrestrial systems, provide prey for many terrestrial and aquatic species, and consume large amounts of plankton. Also, some amphibian species may control densities of other amphibian species. One example is the tiger salamander (*Ambystoma tigrinum)* which, by dint of its high biomass in some ponds, can out-compete other amphibians for food. Another example is the rough-skinned newt (*Taricha granulosa)*, which may preclude some amphibians from inhabiting the same ponds.

Very little is known about amphibian distribution or about the effects of livestock grazing and pesticide use on amphibian populations. Some species, such as tree frogs like *Pseudacris regilla,* are known to be tolerant of grazing whereas others, including the Cascade frog (*Rana cascadae)* and spotted frog, are intolerant. Irrigation can be beneficial or detrimental; irrigation canals or field flooding can provide adequate habitat for egg laying and larval development, but if water is shut off to these areas prior to hatching or metamorphosis, reproduction is lost.

Reptiles

Many species of reptiles may require specific topographic conditions, such as slope and aspect, and are not particularly associated with broad vegetation cover types and structural stages. Many species of reptiles are relatively long-lived and are not reproductively active until three years of age. Loss of individual animals, especially adult females, might have large effects on trends of some populations.

Some species currently listed by agencies as sensitive may be more common or more widely distributed than originally reported. Species of concern that appear to have declining trends but are still common or that are associated with substrates or environmental conditions that are not well distributed in the assessment area were identified. One example is the common garter snake (*Thamnophis sirtalis*) which is widespread in distribution, but appears to be declining in parts of the Basin including southeast Idaho and western Wyoming. Another example is the sharptail snake (*Contia tenuis*), which associates with large, old, rotting logs, and is restricted in range and spotty in distribution. The California mountain kingsnake (*Lampropeltis zonata*) has a patchy distribution and is absent in seemingly suitable habitat.

[25]Recent studies by Green and others (1996) suggest that the spotted frog (prev. *Rana pretiosa*) is really a complex of cryptic species, and that the populations east of the Cascades crest form at least one distinct species from those west of the Cascades crest. The species within the Basin is referred to here as the Columbian spotted frog, *Rana luteiventris.*

Birds

Little information is available on the effects to ground-nesting birds of fire and fire suppression, season of burn, and changes in vegetation pattern resulting from burns and fire suppression. Although general trends have been reported, in the Basin species-specific effects on bird population density and trends from livestock grazing, changes in distribution and density of nest parasites (principally brown cowbird), changes in insect populations, and availability of free water are poorly known. Resource management, including fire suppression and timber management, and the resulting changes in the structure and distribution of vegetation communities has influenced the distribution and abundance of many avian species. For example, the amount of old, single-strata, interior ponderosa pine forests that have been maintained by frequent, low-intensity fires have declined by approximately 80 percent from historic conditions to present. Species associated with this community, such as white-headed woodpeckers (*Picoides albolarvatus*) and flammulated owls (*Otus flammeolus*), have declined in abundance and are considered sensitive by federal agencies. Spotted owls (*Strix occidentalis caurina*) and marbled murrelets (*Brachyramphus marmoratus*), associated with late-successional conifer forests in the Cascade Mountains, likely have also declined in abundance as a result of loss of habitat (Thomas and others 1993), although some mixed-conifer forest habitat for spotted owls may have increased in recent decades on the east slope of the Cascade Mountains as a result of fire suppression. Some non-forest communities and associated vegetation structures have also greatly changed as a result of human activities.

Species associated with native grasslands and shrublands [such as Columbian sharp-tailed grouse (*Tympanuchus phasianellus columbianus*) and sage grouse *(Centrocercus urophasianus)*] have declined dramatically. Conversely, grand fir/white fir communities have increased 964 percent from historic to current; the largest increases have been observed in the stem exclusion closed canopy (1,629%), understory reinitiation (1,100%), young multi-strata (1,676%), and old multi-strata (533%) structural stages. Species associated with or adapted to these cover types and structural stages likely have benefited from their management.

In recent decades, management practices have also reduced some habitat attributes within various cover types and structural stages, primarily large, standing dead trees and large down woody material. The distribution and abundance of many species, including the cavity excavators and secondary cavity users, have been adversely affected.

Neotropical Migrant Birds[26]—Among 132 species of neotropical migratory birds (NTMB) that breed in the assessment area, 38 species have been adequately sampled in breeding bird surveys from which to detect statistically significant population trends over two time periods; 1968-1994 (26 years), and 1984-1994 (10 years). Fourteen species showed significant declines over the 26-year period, and 13 species showed significant declines over the 10-year period. Similarly, 13 and 12 species showed significant increases over those periods, respectively. Seven species [killdeer (*Charadrius vociferus*), olive-sided flycatcher (*Contopus borealis*), willow flycatcher (*Empidonax traillii*), red-winged blackbird (*Agelaius phoeniceus*), western meadowlark (*Sturnella neglecta*), Brewer's blackbird (*Euphagus cyanocephalus*), and Brewer's sparrow (*Spizella breweri*)] showed consistent long-term declines over both time periods. However, five of these seven species occur in low-elevation wetlands or open shrub habitats largely off FS- and BLM-administered lands, and thus are not likely to be heavily influenced by FS or BLM land management activities. The two remaining species are both flycatchers and are both likely influenced to some degree by FS and BLM land management.

Some 16 habitats (vegetation types) were included in the assessment of NTMB status and trends. Riparian vegetation is used by more species (64%

[26]This section is summarized from Saab and Rich (in press).

of all NTMB species) than any other habitat. Other habitats that are used by relatively high numbers of NTMB species include young coniferous forest (38%) and old/mature forest (35%). Among all species with significant 26-year population trends, nine habitats had more species with decreasing populations than species with increasing populations, whereas seven habitats had more increasers. Five of the 16 habitats analyzed with regard to NTMB trends were identified collectively as potentially needing higher conservation priority: riparian vegetation, old forest, shrub-steppe, native grasslands, and juniper woodland. Priority habitats were identified based on declines in populations of associated NTMB species and on the habitats' vulnerability to ongoing management activities. See appendix 5E for information on species that have undergone significant declines and increases over the 10- and 26-year time periods.

Mammals

Small Mammals—Small mammals evaluated in the assessment included those mammals other than bats, carnivores, or ungulates. Species that were considered are collectively found in all of the cover types in the assessment area. Several of the species are exotic to the study area including the Virginia opossum (*Didelphis virginiana*), red fox (*Vulpes vulpes;* a carnivore; native populations are also present), eastern cottontail (*Sylvilagus floridanus*), and nutria (*Myocastor coypus*). Some species, for example many species of ground squirrel in the genus *Spermophillus*, have benefited from changes in cover type like the loss of big sagebrush and the increase in agricultural crops. Habitat for these species may have improved, but they are considered agricultural pests and sometimes are poisoned or killed using other animal control methods. Some species, particularly pocket gophers (*Thomomys* spp.), porcupines (*Erethizon dorsatum*), and mountain beaver (*Aplodontia rufa*), appear to have benefited from conversion of closed-canopy forest to early successional stages. Some small mammals are primarily herbivores, some are omnivores, and others are carnivores and insectivores. Most are considered hosts for a variety of internal and external parasites and prey for a variety of predators. They may also be reservoirs for human disease, such as plague in some species, which is an important consideration in human-animal interactions.

Bats—Very limited information is available on bats of the Basin. Information is lacking on preferred habitats, effects of vegetation alterations, effects of pesticides, and abundance and distribution of bats within the Basin. Insect control was identified as a potential key ecological function for many bat species. Although published accounts refer to bats "controlling" insect populations, few studies are available that quantify effects on insect population abundance. It is known, however, that some species consume vast numbers of insects, including mosquitos and moths. Other ecological functions of bats include the transfer of nutrients to subterranean environments by many bat species and acting as an occasional carrier of rabies.

Human development has favored some species of bat by providing roost sites, hibernaculums, and nurseries. Buildings, bridges, and mines provide habitat for roosting. However, these human-made structures might provide only "sink" habitat for some species; they may entice some bats to roost and hibernate, but other local human activities such as animal control efforts and use of pesticides may cause a net deleterious effect on the bat populations. The effects of changes of distribution and abundance of vegetation communities (for example, interior ponderosa pine) on bats are not well understood. Many species use "deep-furrowed" bark provided by large ponderosa pine. This type of habitat has been reduced. Other conditions providing for bats include mature forests with high snag densities and healthy riparian and wetland areas that provide foraging habitat.

Recreation can potentially adversely affect bat populations, especially if cave nurseries or hibernacula are disturbed. In such cases, seasonal restrictions or cave closures have proven effective measures in avoiding such effects.

Much is being done to help promote conservation of and a positive image about bats to the public. For example, Idaho promotes the building and installing of bat boxes by school classes and offers environmental education, posters, and training courses on bats. Some activities are conducted in conjunction with Bat Conservation International. In Idaho and elsewhere in the Basin, winter cave closures and gating of caves and old mine entrances, which protect bat habitat and prevent disturbances during hibernation, are occuring, usually with cooperation of spelunking groups. Also in Idaho, major studies are being conducted to learn more about the habitat needs and population levels of the Townsend's big-eared bat and the spotted bat.

Carnivores—Many of the carnivores in the Basin are habitat generalists dependent more on availability of prey and lack of disturbance from humans. Examples of such carnivores in the assessment area are the gray wolf (*Canis lupus*), bear [grizzly (*Ursus arctos*) and black (*Ursus americanus*)], wolverine (*Gulo gulo*), and coyote (*Canis latrans*). Others, such as American marten (*Martes americana*) and Pacific fisher (*Martes pennanti*) are closely associated with late-succession conifer forests and riparian habitats or with interior forest environments (Gibilisco 1994). Still other species, such as river otter (*Lutra canadensis*) and mink (*Mustela vison*), occur near or in water and riparian areas. Mustelids (fisher and marten in particular) use large down logs for den sites. Mustelids also use forest landscapes with contiguous or near-contiguous mature or old forest stands.

Distribution and abundance of some carnivores have changed dramatically from historical conditions (Paquet and Hackman 1995). Several species, particularly grizzly bear, gray wolf, and mountain lion *(Felis concolor)*, were and are considered a threat to human safety and livestock production (Curnow 1969; U.S. Department of Interior, Fish and Wildlife Service 1993). Consequently, these species were pursued by government trappers and others from the mid-1800s through the mid-1900s. Methods such as trapping, poisoning, shooting, and the use of bounties were used to reduce the populations. Grizzly bear and gray wolf populations were essentially eliminated from most of the Basin; grizzly bears now remain only in isolated populations. Mountain lion populations were likely reduced in many areas but have increased recently as a result of increased prey populations. Some species such as coyotes, foxes, and skunks increased as a result of reduced competition and removal of their major predators.

The following information is adapted from a longer report commissioned on vertebrate carnivores.[27] Martin and others (1995) also provides information on the legal status and harvest summaries of carnivores in the assessment area.

Ten carnivore species were selected for additional analysis because of issues surrounding their conservation and population viability, and other societal concerns. These species are gray wolf, grizzly bear, black bear, mountain lion, lynx (*Lynx lynx*), wolverine, coyote, American marten, Pacific fisher, and river otter. Long-term conservation of representative carnivores in the Basin is problematic at best. Each species has unique conservation problems that will be difficult to solve.

Many of the large carnivores are habitat generalists and respond well to changes in vegetation. Gray wolves can respond to many vegetation conditions as long as populations of ungulate prey are available. Even though gray wolf, grizzly bear, and other species are protected either by the Endangered Species Act, as amended, or through state regulation, illegal killing and accidental human-caused mortality (misidentification, protection of life, or highway kill) still occur. Consequently, long-term conservation of many of the large carnivores will depend on the attitudes of the public.

Smaller carnivores generally do not garner such highly negative public attitudes, but nonetheless have their own conservation challenges and susceptibility to human activities. Species such as the

[27]Martin and others 1995.

marten and fisher select for late-successional forests which are becoming more limited. Wolverines may be affected by increasing human disturbance of subalpine environments and accidental mortality from trapping. Lynx select for early-seral stage, boreal forest habitats supporting high populations of snowshoe hare (*Lepus americanus*) and other small mammals, as well as landscapes also having older forest mosaics. Because they are at the southern portion of their range in the assessment area and therefore have low population densities, incidental mortality of lynx from trapping, illegal harvest, and road use may adversely affect populations, particularly during population lows. Lynx are very scarce in Idaho, and whether or not they are maintaining themselves along the Montana side of the Rocky Mountains and in northeastern Washington is disputed. The river otter is a habitat specialist dependent on riparian areas that are associated with clean rivers and streams with productive fish populations. Extensive degradation of water quality and riparian communities has reduced habitat for this species.

Conservation themes that simultaneously benefit several species of carnivores include:

- conservation of late-successional forests,
- preservation of large or inaccessible blocks of habitat (with low human disturbance),
- protection or restoration of low elevation riparian and forested habitats to link or connect source populations,
- maintenance of adequate prey populations and their specific habitat requirements, and
- reduction in illegal and accidental killing including accidental take of non-target species during legal hunting, legal trapping, or predator control programs.

Development and use of roads is a primary factor that influences distribution and abundance of most carnivores. Increased access to remote areas results in higher carnivore mortality from hunting, including potential misidentification of species (grizzly bears for black bears, gray wolves for coyotes), and illegal killing (U.S. Department of Interior, Fish and Wildlife Service 1993). Roads also act as significant barriers to movement for some species although the effects of roads on animal movements are not well documented for species other than gray wolf or in ways that helps improve understanding of carnivore population dynamics. Access management of roads in forested, non-forested, and riparian environments is critical to conservation of carnivores.

Many of the carnivore species are very wide-ranging and their conservation likely will require the cooperation of all land managers including private landowners. Close and effective cooperation with Canada is also imperative since many of the species range across the border. Canada contains more suitable habitat and larger populations of some species (lynx, grizzly bear, and gray wolf).

Many area- or site-specific management quandries and problems associated with carnivores simply cannot be resolved at the broad scale. As with other species groups, site-specific consultation with local experts and analysis of local conditions need to be conducted. Management of carnivores should be considered in the full context of their ecosystems while addressing such local issues as restoration of ecological processes and control of the adverse effects of poaching.

Ungulates—Livestock grazing on BLM- and FS-administered lands is an important issue that affects the management of wild ungulate populations. Livestock grazing can be compatible if appropriately managed (that is, when both grazing season and grazing intensity are considered). Two approaches to grazing considered in this assessment emerged from literature reviews and panel discussions: (1) maintaining adequate forage is the key to ungulate management, and (2) cover, especially on winter ranges, is important to offset the poor nutritional quality of forage in winter. The common factor with both views is the vulnerability of wild ungulates. As well, roads play a major role in affecting ungulate vulnerability during all seasons of the year, not just during hunting season.

Ungulates provide an important prey base for most of the large carnivores and provide carrion for many scavengers. Bison *(Bos bison)*, as an example from the Greater Yellowstone Ecosystem portion of the Basin, provide carrion for many vertebrate scavengers and invertebrates as well. Elk (*Cervus elaphus nelsonii*) and moose (*Alces alces*) also provide carrion in this way. The invertebrates that inhabit the carcasses provide a source of food for insectivores, such as bluebirds. Deer and elk are also considered important species for subsistence by most of the American Indian tribes within the assessment area. Woodland caribou probably were never abundant south of Canada, and were never legally hunted. They are endangered with an active protection, reintroduction, and recovery program underway.

The following is abstracted, in part, from a contract report on selected ungulates in the assessment area.[28]

Ungulates were identified for additional analysis to address management concerns, social (recreational hunting) and other public issues, tribal concerns, and economic importance in the Basin. Three ungulate species, moose, black-tailed deer (*Odocoileus hemionus columbianus*), and bison, were not included in the analysis because of limited distribution or rarity of occurrence within the assessment area. Issues and associated environmental correlates were identified, and habitat models for the remaining species [elk, mule and white-tailed deer (*Odocoileus hemionus* and *Odocoileus virginianus*), California and Rocky Mountain bighorn sheep (*Ovis canadensis californiana* and *Ovis canadensis canadensis*), mountain goat (*Oreamnos americanus*), American pronghorn *(Antilocapra americana)*, and woodland caribou (*Rangifer tarandus caribou*)] were reviewed.

All or most of the Basin is occupied by one or more ungulate species. Ungulates are important both for social reasons (recreational hunting and viewing) and for economic returns to local communities through expenditures during hunting and tourism seasons. For example, approximately 450,000 hunters pursue elk annually within the Basin, which results in an economic effect of about $225,300,000 and 3,467 jobs (Teisl and Southwick 1995). Although the permit numbers may be limited for some of the other ungulate species, for example, mountain goat or bighorn sheep, at least some individuals or corporations are willing to pay from $50,000 to over $300,000 for the opportunity to harvest a single bighorn sheep. Other than hunting, viewing ungulates is important to many people. In some areas, congregations of ungulates on winter ranges provide the public the opportunity to see many individuals.

Many ungulate species are important to American Indians for subsistence. Twenty-two tribal areas of interest were identified in the Basin. Elk and/or deer occur in all of these areas and are hunted by tribal members. Bighorn sheep have been the main source of subsistence for Shoshone-Bannock-Paiute Indians in Idaho, although elk, deer (both mule and white-tailed), pronghorn, and mountain goats also have been important.[29]

Similar to states and rural communities, hunting wild ungulates on tribal reservations can provide economic returns to tribes and stimulate active management for these species. Traditional hunting areas for the tribes also include considerable public lands, and in some instances, result in competition for the annual harvest with the general public hunting seasons.

In some instances, competition for forage between domestic livestock and wild ungulates, and use of agricultural crops by wild ungulates present a different economic issue. Reported damage to haystacks, alfalfa fields, and fruit orchards often results in damage claims to states. States expend funds to fence haystacks and orchards to prevent deer or elk entrance, and special hunts are held to reduce ungulate population numbers. Another

[28]Lyon and others 1995.

[29]Personal communication. 1995. Allan E. Thomas, Fish and Wildlife Biologist. U.S. Department of Interior, Bureau of Land Management, Idaho State Office, 3380 American Terrace, Boise, Idaho 83706.

social issue is disease transmission from domestic sheep to wild sheep. This has resulted in severe reductions of wild sheep populations in the Basin.

Ungulates of the Basin are important ecologically because of their influence on vegetation. For example, large numbers of elk in southwestern Montana and at least that portion of the Greater Yellowstone Ecosystem that lies within the Basin have severely reduced riparian willow cover along many streams and rivers by excessive grazing. Large ungulates also provide carrion and prey for many of the large carnivore species such as gray wolf, mountain lion, and bears (both black and grizzly). Carrion is also important to many scavengers such as wolverines, ravens (*Corvus corax*), and magpies (*Pica pica*).

Commodity use of public lands, such as mining, livestock grazing, and timber harvest, affect habitat for many of the ungulate species. Land management often alters vegetation composition and structure and can be beneficial to ungulates if their habitat requirements are considered. However, some human demands, such as recreation and residential development on winter ranges might conflict with management for ungulates.

Threatened, Endangered and Candidate Species

There are 47 terrestrial vertebrate taxa (species or subspecies) listed as endangered, threatened, or as Category 2 candidates (C2) under the Endangered Species Act, as amended (table 5.12). No vertebrates are listed as Category 1 candidate (C1) or proposed by USFWS as threatened or endangered (table 5.8).

For this assessment, U.S. Fish and Wildlife Service provided species status reports on selected threatened, endangered, and candidate species. Those reports are summarized here.

Endangered Vertebrate Species—

Peregrine Falcon (*Falco peregrinus*)—Populations experienced dramatic declines between 1946 and 1975 as a result of pesticide use, primarily DDT and its metabolites DDE and dieldrin. These chemicals accumulated in peregrine falcons and their prey. Mechanisms of the chemicals induced eggshell thinning which caused reproductive failure and nearly caused extirpation (Pagel 1995). The Pacific States Recovery Plan was approved in 1982 and has aided recovery.

Current population survey information within the assessment area indicates slow increase in population densities. Since 1979, 47 new nests have been located in the assessment area. Reproductive success has been fair to good, with higher rates of productivity reported now in Idaho than in previous years, where numbers of young per known nest site averaged 1.15 (N = 190 nests) over the last 11 nesting seasons (Pagel 1995). In Idaho, the species has recovered sufficiently that it is proposed for down-listing to threatened status.

Eggshell thinning continues to be a problem in some areas, particularly Oregon. Pagel (1995) reported that eggshells were thinner by approximately 11 percent, 12 percent and 16 percent in the Yellowstone, Idaho, and Oregon sites within the Basin, respectively, as compared with the average thickness of natural, unaffected eggshells. Levels of eggshell thinning exceeding 17 percent were found in peregrine falcon populations that are currently declining or have been extirpated (Peakall and Kiff 1988).

The population of peregrine falcons of the Basin has been artificially augmented since 1980. Approximately 1,062 birds have been artificially raised at hack sites in the Basin. However, two primary threats remain: contaminants and disturbance of natural nest sites. And at least in Idaho, another potential concern is avian predation of young, especially by great horned owls.

Whooping crane (*Grus americana*)—This migratory species winters outside the Basin (southeast Texas coast) and breeds in Wood Buffalo National Park in Alberta, Canada, and Grays Lake National Wildlife Refuge in Idaho. A third, non-migratory flock is being established in Florida. Natural occurrence in the assessment area is currently

Table 5.12— Threatened (T), endangered (E), and candidate (C1 and C2) vertebrate species of the Basin.

Scientific Name	Common Name	USFWS Status
Amphibians

Spermophilus washingtoni	Washington ground squirrel	C2
Ursus arctos	grizzly bear	T

limited to the Grays Lake site. This population winters at Bosque del Apache National Wildlife Refuge in New Mexico. Only three birds use the Grays Lake site. Primary habitat is shallow, wet meadows and their adjacent uplands with minimum human disturbance. Cross-fostering with sandhill cranes is being used to augment the population at Grays Lake National Wildlife Refuge. This population has been declining as a result of poor or improper imprinting on foster parents to the point where the Grays Lake site has been removed as critical habitat and the birds designated as "experimental nonessential" (U.S. Government 1996b).

Whooping cranes likely were never common in the Basin and were nearly extirpated for plumage in the early 1900s. Continued threats to recovery are loss of wetlands, illegal shooting, collisions with powerlines, and disease.

Gray wolf (*Canis lupus*)—Wolves were nearly exterminated from the Basin between the mid 1880s and early 1900s (Fritts and others 1994, Lauffer and Jenkins 1989). Individuals were killed by shooting, poisoning, and trapping. Prior to Euro-American settlement of the western United States, bison, elk, bighorn sheep, deer (mule and white-tailed), and moose were the primary prey of wolves. During and following settlement, domestic livestock were introduced in large numbers, and native ungulates were killed for food and hides. This resulted in drastic declines in the native prey base, reduction in natural habitats, and increases in human-wolf encounters.

Public attitudes toward wolves have slowly changed since the 1970s with increasing interest in wildlife, conservation, and the environment. As a result of public agency management, wild ungulate populations, especially elk and deer, have increased. As a result of changing attitudes towards predators such as wolves in Canada, reductions in human-caused mortality allowed wolves to recolonize northwest Montana in the 1970s and 1980s and Washington and Idaho in the 1990s. Reintroduction of wolves in Yellowstone National Park and in the Central Idaho Wilderness (Central Idaho Gray Wolf Recovery Area) were made in winters of 1994-95 and 1995-96. All reintroductions appear successful with very minor impacts to humans. Reintroductions were also made in the Sawtooth Mountains of Idaho in 1995 and 1996. The Central Idaho Recovery Area and the Northern Rocky Mountain Recovery Plan (U.S. Department of Interior, Fish and Wildlife Service 1987) are two other ongoing efforts to recover the population in the assessment area.

Wolves can successfully respond to most changes in vegetative cover types and structures. Their primary needs are available ungulate prey, available den sites, and freedom from human persecution (Fritts and others 1994). The major threats to recovering gray wolf populations are continued persecution and illegal killing.

Woodland caribou (*Rangifer tarandus caribou*)—A small population of approximately 60 of woodland caribou remains in the Selkirk Mountains of northeastern Washington and northern Idaho. The range of this herd extends into southern British Columbia. The population decline, which began in the mid-1950s, resulted primarily from illegal killing. The recovery program for this population began in 1987 with an augmentation of 24 animals, followed by introductions in 1988 and 1990 of 24 and 12 animals, respectively. A fourth introduction is currently underway.

Early winter habitat has been described as low elevation, late-succession cedar/hemlock forests. Later in winter, animals move to high-elevation, wind-blown slopes of late-succession spruce/fir forests where they seek fallen arboreal lichens.

Threats to the population include habitat alteration as a result of timber harvest or wildfire; a restricted range which, when coupled with predation, has greatly increased risk to long-term viability; and low population numbers. In Idaho, chief threats are timber harvest, illegal killing, and highway road-kill during migration. Disturbance by winter recreation is also a threat.

Threatened Vertebrate Species—

Bald eagle (*Haliaeetus leucocephalus*)—The bald eagle was listed by USFWS as threatened in Oregon and Washington and endangered in Montana, Idaho, Wyoming, and Utah (within the Basin) in 1978. The endangered status was proposed for down-listing to threatened in 1994 and was down-listed in 1995. Major declines in the nesting population in the Basin began in the early 1900s and continued through the 1960s. Causes were direct killing, direct and secondary losses as a result of chemical contaminants (DDT and DDE), disturbance during nesting and loss of nesting habitat.

Nest territories are typically associated with large bodies of fish-producing water. Bald eagles use the same territory in successive years. Although multiple nests may be constructed within one territory, bald eagles show a strong fidelity to the same nest. In the Basin, nest stands consist largely of coniferous trees with large branches to hold the nest, though cottonwood trees are also used, as in the South Fork area of the Snake River, Idaho.

The Pacific Northwest accounts for 25 percent of the wintering bald eagles in the contiguous 48 states. Most wintering habitat is associated with prey sources of fish, waterfowl, or carrion. An existing recovery plan for Pacific bald eagle (U.S. Department of Interior, Fish and Wildlife Service 1996) has been instrumental in mobilizing conservation activities for the species in the assessment area.

Grizzly bear (*Ursus arctos*)—Historically, the grizzly bear was present over most of the Basin. The population was reduced from over 50,000 to less than 1,000 bears between 1800 and 1975 (U.S. Department of Interior, Fish and Wildlife Service 1993). The reduction was a result of human expansion into and development of the western United States. The primary causes of the decline were trapping, unregulated hunting, and killing while protecting human life. The grizzly bear was listed as threatened in 1975. A recovery plan was approved in 1982 that identified six recovery areas to be managed for grizzly bears (Cabinet-Yaak, North Cascades, Selkirks, Bitterroots, Northern Continental Divide, and Yellowstone Grizzly Bear Recovery Areas, sometimes also referred to as Ecosystems). All six of these are totally or partially within the Basin. Population estimates for the six zones range from 600 to 1,100 bears with 95 percent in the Northern Continental Divide and Yellowstone Grizzly Bear Ecosystems.

Human-induced mortality is the primary threat to grizzly bear recovery. Management actions or lack of actions that are threats include increasing access with road and trail construction and lack of sanitation management in some recovery areas. Food and garbage associated with residential development on the forest/urban interface, developed campgrounds, and other recreation activities can result in bears becoming conditioned to human foods. In many cases, such conflict causes bears to be destroyed. Lack of interchange of bears between populations may also be a long-term threat to many of the populations.

Northern spotted owl (*Strix occidentalis caurina*)—The northern spotted owl nests in late-successional forests on the east slopes of the Cascade Mountains. The majority of nest sites are in late-succession Douglas-fir or mixed conifer vegetation. In some cases nest sites are in younger vegetation but with structural components that are found in older stands. Most of the low and mid-elevation forest habitat is fragmented as a result of natural factors (for example, soils, fire, and unforested high elevations), and timber harvest.

Marbled murrelet (*Brachyramphus marmoratus*)—No known nesting of murrelets has been recorded within the Basin. Reports of individuals have been recorded near the crest of the Cascade Mountains. The species is expected to be present within 55 miles of marine environments and is thus barely within the assessment area just east of the crest of the Cascade range in Washington. Loss of nesting habitat is the major threat to marbled murrelets within the Basin.

Species of Tribal Interest

Vertebrates of interest to the American Indian tribes within the Basin were analyzed by comparing historical vegetation cover types and structural stages with the current condition. Environmental correlates other than vegetation were not considered in this analysis. The Science Integration Team identified 71 terrestrial vertebrates as species of special tribal interest (TS 1995). Species were not listed by specific tribe; therefore, all species were analyzed for all tribal areas regardless of whether or not the species range overlapped a specific tribal area. Decreasing trends in suitable environments were exhibited by 63 percent of the species and increasing trends by 37 percent. Of those that decreased, 50 percent decreased more than 20 percent and of those that had increasing trends, 52 percent increased more than 20 percent (TS 1995) (also see tables and appendices for information on trends of suitable environment).

Areas Containing Populations of Large, Wide-Ranging Carnivores

The overall distribution of most of the large carnivores (secondary predators, or tertiary consumers) has declined and individual populations have decreased since European settlement in the Basin and other parts of the western United States. Large carnivores of the Basin include six species: grizzly bear, American black bear, gray wolf, mountain lion, lynx, and wolverine (a mid-size carnivore also considered here). All of these are large-bodied and have large home ranges.

Many parts of the Basin continue to support populations of black bear and mountain lion but few areas still contain grizzly bear and gray wolf. Information on distribution and density of wolverine in the assessment area is lacking, although some studies have been conducted in the Sawtooth Mountains of Idaho. Four areas, the Yellowstone, North Cascades, Cabinet-Yaak, and Selkirks Grizzly Bear Recovery Areas, each contain all of the six species but have low numbers of either grizzly bear, wolf, and/or wolverine. Only the Northern Continental Divide Grizzly Bear Recovery Area (which includes Glacier National Park, the Bob Marshall Wilderness, and the North Fork of the Flathead River) and possibly parts of the Cabinet Mountains contain populations of all six species that are well distributed and abundant enough to allow studies to investigate the relations among the above species. Historically, much of the Basin, especially the forested parts, supported populations of all of these large predators.

Mountain lions remain well distributed within the forested habitats in the Basin. Human encounters with mountain lions have increased over the past few years, possibly as a result of increased numbers of mountain lions or of increased human activity in mountain lion habitat. Black bears are also well distributed in the forested ecosystems within the Basin. All states continue to offer sport hunting of black bears and most, if not all, offer permits for mountain lions.

Within suitable vegetation cover types in the Basin, lynx and wolverine are widely distributed although their total numbers and local density have been reduced significantly. Within the Basin, lynx are on the southern extension of their range (Koehler and Aubry 1994). Their distribution in the assessment area may have retracted northward (Koehler and Aubry 1994). The largest concentration of lynx in the contiguous 48 states has been identified in north-central Washington (Brittell and others 1989). Smaller, isolated populations remain across northern Washington but in some cases in very low numbers as compared with historical levels. Most of these individuals are connected to populations and habitat in British Columbia. Lynx are also present in Idaho and Montana and are still trapped (two permits per year) in Montana. Wolverine are reported over much of the Basin, but are found in very low densities except in parts of the Rocky Mountains (Banci 1994).

The northern Rocky Mountains (Glacier National Park and adjacent wilderness areas) and Yellowstone National Park have succeeded in maintaining grizzly bear populations because of associations with protected recovery areas and protection against trapping, poisoning, and killing during settlement of the western United States. Although gray wolves were nearly extirpated from all of the lower 48 states, recolonization of the Northern Rocky Mountains began when the Canadian government relaxed their predator control programs for wolves allowing wolf populations to expand and disperse southward from Canada (Fritts and others 1994). Changes in human attitudes toward wolves and the reintroduction of wolves increase the chances that some of the dispersing animals will survive.

Grizzly bears are present in five of the six currently designated Grizzly Bear Recovery Areas (the Bitterroot Recovery Area is the exception). The North Continental Divide and Yellowstone Recovery Areas have grizzly bear populations that are of sufficient size to study relations and interactions with other species such as predators and scavengers. The Yellowstone Recovery Area may not have populations of gray wolves (reintroduced in 1995) or lynx of sufficient size to investigate interactions between species. The Cabinet-Yaak Recovery Area may have sufficient populations, although the grizzly bear population is still being augmented, of all six predators to warrant studies of their interactions but no such research is currently being conducted.

There are ongoing studies in northern Montana on grizzly bears, gray wolves, and mountain lions. Some preliminary anecdotal information from these studies relates to how these three species interact. Four cases of wolves killing mountain lions but not consuming them have been reported. There has been one report of several wolves pursuing a grizzly bear sow with cub and possibly killing and consuming the cub. Other reports are of wolves killing coyotes.[30]

In previous studies, mountain lions tended to remain with their kill, primarily ungulates, for more than one week until they eventually completely consumed the animal. In northern Montana, however, mountain lions tend to abandon their prey following the kill and a single meal. Such observations suggest that other scavengers, such as magpies and ravens, have a continuous source of carrion when such carnivores are present.[31]

There is speculation[32] that mountain lions began to occupy low elevation areas where wolves were

[30]Personal communication. 1995. Daniel Pletcher. University of Montana, School of Forestry, Bozeman, Montana 59717.

[31]Lyon and others 1995.

[32]See footnote 31.

eliminated and took advantage of prey sources. With recovery of wolves and their occupation of low elevation valleys, mountain lions will likely recede to their more traditional, rougher terrain habitat.

Paquet (1992) indicated that where prey resources are not limiting, that is where healthy populations of deer, moose, and elk are present, little competition for food occurs among large carnivores. Paquet (1992) found that where coyotes and wolves occupied the same area and elk, white-tailed deer, and moose were present, coyotes tended to prey primarily on deer and occasionally on young elk, and wolves selected elk and white-tailed deer and, secondarily, moose. Coyotes also tended to follow wolves to scavenge wolf kills. Periodically, wolves killed coyotes, but did not search them out. Similar differences in prey preference have been noted in northern Montana[33] where mountain lions prey more on elk, wolves on deer, and grizzly bears on moose calves. Wolverines are primarily scavengers (Banci 1994) and benefit from ungulate kills made by other predators. Recent (1995) information from Yellowstone National Park[34] on reintroduced wolves indicates that grizzly bears are displacing wolves from carcasses.

Large carnivores can also influence their environment in other ways. Grizzly bear digs in alpine meadows currently are being investigated relative to nutrient cycling. Preliminary results indicate higher levels of nitrogen in digs as compared to similar areas with no recent digs. Some plants, especially glacial lily, are more robust and vigorous within digs.

Distribution and abundance of most of the large-bodied carnivores in the assessment area have decreased since settlement by Europeans. Very few studies have evaluated effects of changes in distribution and abundance of these large animals on other species or the environment. This change, in turn, has likely influenced the distribution and abundance of scavenger species of vertebrates throughout the assessment area. There is very little information that suggests populations of prey, particularly ungulates, have increased as a result of reduction of predator abundance and distribution. Many ungulate populations, such as deer and elk, have dramatically increased since decline of predators, but this is largely a result of habitat enhancement, or regulation of hunting. Other potential effects of the long-term decrease in large carnivores might include reduced competition with other smaller predators, such as coyotes, raccoons, and skunks, which allows those species to increase in distribution and abundance.

Ultimately, the distribution and health of large carnivore populations of the Basin can be thought of as an index of the status and distribution of wild areas in the western United States. These species are sensitive indicators of the degree of human-caused change of wild lands. From a human perspective, they also play critical roles in American Indian tribal lore and religion and are living embodiments of places that are felt to be still truly wild.

Implications of Management Activities on Terrestrial Vertebrates

Distribution and abundance of species can be influenced by many factors. Some of the factors are well understood (for example, reductions in cover type or structure affects almost all species to some degree). The northern spotted owl provided the classic example. Reductions in late-succession, conifer forests west of the Cascade Mountains resulted in the listing of the species as threatened under the Endangered Species Act. Other examples include the broad-scale use of pesticides for vegetation or insect control resulting in downward trends in species such as peregrine falcons and bald eagles. Throughout the expert panels on vertebrates, threats to species or groups were identified. The following section describes threats to each taxonomic group.

[33]Personal communication. 1995. John Weaver, carnivore panelist, Missoula, Montana 59807.

[34]See footnote 33.

Amphibians—Most of the amphibians present in the Basin have life cycles that include aquatic conditions as well as terrestrial conditions. The larval stage of most salamanders and frogs occurs in an aquatic environment.

Loss of wetlands has the biggest adverse effect on amphibians. The direct loss of habitat through development for residences or agriculture has had major adverse effects. Leonard and others (1993) estimated that between one-third and one-half of the wetlands in Oregon and Washington have been drained or filled.

Introduction of exotic species has increased predation in many areas and resulted in lower population numbers or elimination of some species in waters where the predators are present. Many high-elevation lakes have been stocked with spiny-rayed fish, primarily trout, over the past 50 years. In lakes with breeding amphibians, the high biomass of young provided abundant food for fish, but as a result, many amphibian species declined. The introduction of bullfrogs in some low elevation ponds has also increased predation on larval and adult stages of many amphibian species. Introduction of carp in some areas removed aquatic vegetation and in turn limited both egg-laying habitat and habitat for plankton and small insects used as food.

Some species, such as the Great Basin spadefoot (*Spea intermontana*) and tiger salamander (*Ambystoma tigrinum*), have a wide tolerance for water quality including dissolved oxygen content and temperature. Other species, like the Idaho giant salamander (*Dicamptodon aterrimus*), have a lower range of tolerance. Increased sedimentation resulting from land management practices, whether agricultural or forestry, can fill crevices and interstitial spaces or other niches and affect eggs and larval stages directly and indirectly by reducing aquatic insect production and thus, limiting food.

Irrigation can be both beneficial and detrimental. Large dams and irrigation reservoirs can result in drawdowns that cause egg masses to dry. Irrigated areas may provide suitable conditions for egg laying but many dry up before the eggs hatch, resulting in loss of production for some species. For other species, irrigating fields increases their habitat; the tiger salamander and Great Basin spadefoot are examples.

Roads can have direct effects on individual amphibians through mortality, especially during dispersal. Roads can also result in increased sedimentation of aquatic systems which influences both food and reproduction.

Herbicides and other pesticides also have both direct and indirect adverse effects on amphibians. Much information is available on this topic. Livestock management is another area that may adversely affect species by altering water quality (run-off from feed lots), changing native vegetation, trampling, and altering native methods. The last threat relates to collection and use of various amphibians for "pets," for science industries, and, in some cases, for fish bait. Many states have passed statutes to prevent these practices.

Reptiles—Large dams have resulted in the loss of considerable habitat for reptiles, especially along the Snake River. In addition to loss of riparian and aquatic habitat, for some species, most of the pool filling occurs in winter when many species are communally hibernating. The result is loss of many individuals and perhaps even local extirpation of some species, such as the longnose leopard lizard (*Gambelia wislizenii*) and striped whipsnake (*Masticophis taeniatus*), from parts of their range, although the leopard lizard may not be in any particular trouble on Idaho BLM land. Operations of large dams and associated regulated rivers can also result in drawdowns at times critical for some species such as garter snakes.

Conversion of native vegetation to agricultural use, livestock grazing, draining of wetlands, and use of pesticides in the Basin has resulted in degradation of environments or loss of habitats for some reptile species. Livestock grazing and associated activities have altered plant species composition and introduced many exotics, resulting in habitat degradation and loss for the sagebrush lizard

(*Sceloporus graciosus graciosus*) and western terrestrial garter snake (*Thamnophis elegans*). Loss of wetlands has directly reduced populations of painted turtle and western pond turtle.

In some of the "desert" areas or sand dunes, off-road vehicle use has become a major threat to reptiles. Roads and off-road vehicles result in direct mortality and in indirect losses by fragmenting habitats. Populations of longnose leopard lizards have been affected by roads and road use in parts of their range. Roads fragment some reptile habitats and can become barriers to movements of some species, particularly burrowing (fossorial) species such as the longnose leopard lizard, striped whipsnake, and gopher snake (*Pituophis catenifer*). Gopher snakes migrate seasonally between habitats and are frequently killed on roads. Many species warm themselves on roads and are run over. In addition to direct mortality, road construction and mining activities for gravel and other materials for road surfaces can destroy habitats and hibernacula for species such as the western fence lizard (*Sceloporus occidentalis*) and western rattlesnake (*Crotalus viridis*).

In the past, some species such as the western pond turtle *(Clemmys marmorata)* were captured for food and trade. Most states now provide some protection. Capture for pets may be a problem with some species, such as the horned lizards and Mojave black-collared lizards (*Crotaphytus bicinctores*). Some of these species including common garter snakes and horned lizards were abundant in the past and are still common, but their numbers and distribution have declined.

Fire suppression has induced conifer encroachment on certain shrub habitats and has contributed to loss of habitat for reptiles. Additionally, fire suppression and intensive grazing has altered the vegetation structure of some of the shrub habitats. If intensive fire occurs in these habitats under current conditions, the shrubs over large areas may be lost and the area converted to grassland; this would reduce habitats for some species closely associated with shrub habitats, including the Mojave black-collared lizard.

Mammals and Birds—The diversity of species and habitat uses between these two groups is such that actions that are threats to one species may be beneficial to others. For example, some of the ground squirrels may have benefited from conversion of native arid shrub and grassland vegetation to agricultural lands while at the same time the pygmy rabbit (*Brachylagus idahoensis*), which inhabited the same areas, has been reduced to isolated populations and extirpated in parts of its range.

In forested environments, species that more heavily depend on late-succession forests decline as that structure declines, and species tied to early-succession cover types likely benefit. Threats to species that require late-forest succession and associated structural components such as large snags and down, woody material include the reduction or loss of these components, changes in wood decay rates, and declines in insect (primarily ant) populations (Bull and others 1995). The demand for wood products has reduced these components in parts of the assessment area. Anecdotal information on declines in numbers of bats in local areas is related to reduction in the number of large snags.

Fire suppression and intensive forest management has altered much of the forested areas in the Basin area. Associated with this harvest is increased access into areas of previously low human use. These largely inaccessible areas were refuges for some species, like the wolverine and grizzly bear, that are sensitive to human disturbance. Road construction and travel has created barriers for some species. It has also resulted in indirect mortality of some species, increased disturbance during critical periods of life cycles; and increased mortality during recreational hunting and trapping.

Livestock grazing can be a threat to some species, beneficial to some, and neutral to others. The degree or intensity of grazing, both in removal of vegetation and in soil compaction, determines the effect on most species. Species such as ground squirrels, moles, and some shrews are adversely affected by soil compaction and trampling of runways by livestock.

Agricultural practices other than livestock grazing have similar effects. Some species, such as some of the voles *(Microtis* spp.), benefit from an increase in agricultural development but are adversely affected by increased tilling. Use of pesticides and other control measures associated with agricultural production is detrimental to most species either directly or indirectly through reduction of forage or animal prey. Many of the bat species are suspected to be adversely effected by pesticide use for control of forest insects. In some cases non-target species such as nocturid moths are killed; these are important prey for some bats. Some species, such as gophers, ground squirrels, and jackrabbits that increase as a result of agriculture, are considered pests.

Animal damage control through livestock, forest management, or agricultural practices can be a threat to many species. Control of predators, such as coyotes, occasionally may result in mortality of some non-target species including wolves. There have been cases of poisoning for gophers or other small mammals that have resulted in secondary poisoning of scavengers feeding on carcasses. Predator control resulted in extirpation of gray wolves from the Basin by the mid-1940s. The northern portion of the assessment area is being recolonized by wolves both naturally and through reintroduction programs, but human attitudes toward wolves in some areas remain negative and illegal killing still occurs. Numbers of grizzly bear have been significantly reduced but they have not been extirpated in remote areas. Recovery of these species is difficult because of public attitudes and illegal killing.

Recreation activities can present threats to some of the species. Activities can be and are compatible in many areas if the needs of certain species are addressed and managed. Development of large resorts for alpine or cross-country skiing can result in loss of alpine habitat or disturbance of species during winter. Snowmobiles provide access into areas that historically were free of human disturbance during winter. Some species, such as wolverines in high cirque basins, may be easily disturbed and displaced from food sources by snowmobilers. Access into high elevation, deep snow areas by snowmobiles compacts the snow and allows other predators, such as mountain lions and coyotes, into areas where historically they were not present. In some cases this can increase competition on limited prey. Wintering concentrations of ungulates can be disturbed by skiers, snowmobilers, or snowshoers. During summer, this level of disturbance may not be a problem but, in winter, quality food is limited, and movements by large animals require use of calories that cannot be replaced. Under certain weather conditions, additional movements may result in higher-than-normal winter mortality or loss of fawns and calves. Much of this disturbance by recreationists is unintentional.

Summer recreation use, especially in the backcountry, can result in habituation of some wildlife species typically repelled by human presence. In some areas, both black and grizzly bears become conditioned to foods left unattended in camps or garbage left in campsites. Typically, conflicts between humans and bears result in destroying the individual bear.

Recreational hunting is also considered a threat to some species. During black bear seasons, misidentification can result in killing of grizzly bear. Also, most states allow coyotes to be killed during any time of the year, and occasionally gray wolves are killed because of misidentification. Legal seasons for hunting mountain goats may present problems in some areas where hunting limits are too liberal.

Roads, especially interstate highways or other multi-laned, high-traffic-volume roads may present barriers to several species and might directly cause mortality. At least two gray wolves have been killed by vehicles in the last five years. In some cases, large highway systems are fenced, preventing movement of some species. Because of fencing, some ungulate wintering ranges are inaccessible to many animals. The animals, therefore, winter in areas that do not provide sufficient resources.

Loss of wetlands through filling for development or draining for agriculture has reduced habitat for most species of waterfowl, many shorebirds, amphibians, and some mammals such as muskrats.

Trends in Vegetation Cover Types and Structural Stages

In previous sections we have presented results on taxonomic groups and species functional groups. In this section we explore terrestrial ecology of the Basin from the standpoint of habitat–principally, trends in vegetation cover types and structural stages. We discuss shifts in habitat area for vertebrate species; implications of broad-scale vegetation changes for species using native grasslands, native shrublands, and old forests; and implications of habitat fragmentation. We then discuss modeling of mid-scale habitat patch trends, focusing on mid- and old-structure stages of forests. Detailed results of modeling of historic and current vegetation conditions are presented in the Landscape Dynamics chapter of this report. We use the term vegetation community here to refer to vegetation cover types and structural stages.

Shifts in Habitat Area for Vertebrate Species

Four hundred and sixty-three vertebrate species were analyzed for changes in habitat area over time across the Basin (TS 1995). Primary habitat for 63 percent of these species had increased or had not changed in area from estimated historical values across the Basin, while habitat for 38 percent of the species had decreased more than 10 percent from the historical area (fig. 5.3; also see TS 1995). The decline in estimated habitat area was greater for birds (44%) and reptiles (41%), than for amphibians (26%) and mammals (25%).

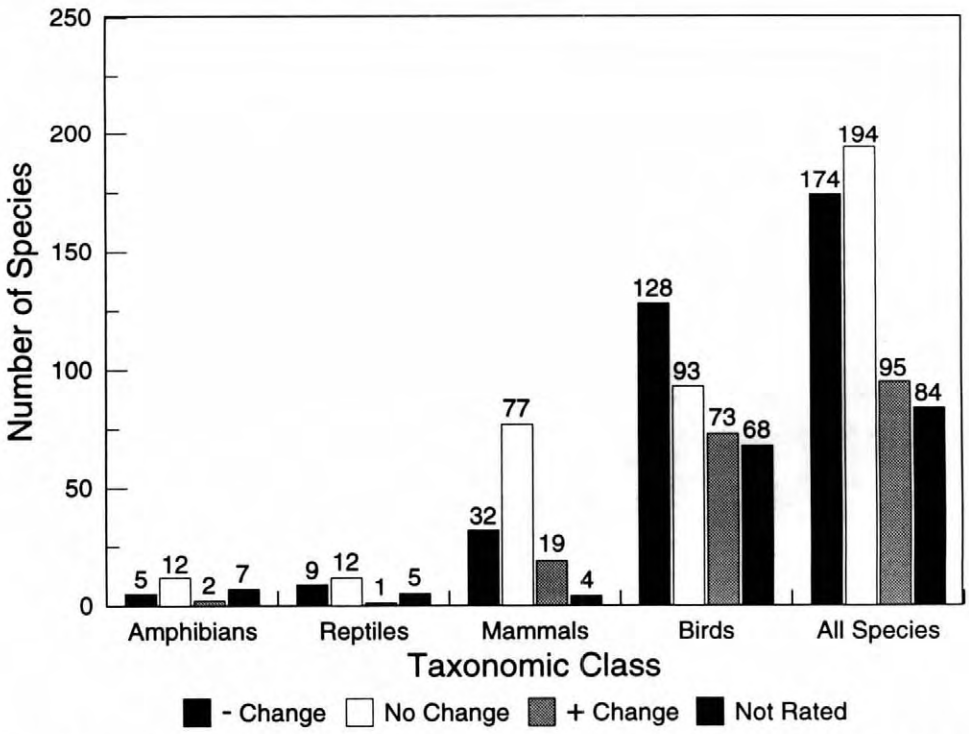

Figure 5.3— Trends in primary habitat change for vertebrates in the Basin since the early 1800s. "No change" was defined by ±10% change in area from the historic area, "negative change" was a >10% decrease in area, and "positive change" was a >10% increase in area. Primary habitat was estimated as the sum area of cover type/structural stage map polygons in Ecological Reporting Units (ERUs)in which the species range intersected ≥10% of the ERU. Species occurrence that was peripheral, occasional, accidental, or with restricted ranges was not rated.

However, estimates of numbers of vertebrate species affected do not tell the full story; further evaluations of species closely associated with specific habitats or environmental conditions revealed additional patterns. Species closely associated with agricultural areas; exotic rangeland vegetation (for example, cheatgrass); stand initiation and young phases of forest development, especially montane cover types such as grand fir and Douglas-fir; and juniper-sagebrush woodlands generally showed gains in habitat area. Species showing habitat losses over the historical period were closely associated with ponderosa pine cover types (especially single-story old-forest stands); other single- or multi-story old-forest structural stages of forest development; native grasslands and shrublands, especially native bunchgrass, sagebrush and other shrub-steppe habitats; riparian cottonwood-willow, and herbaceous and shrub wetland habitats; and large-snag, defective-tree, or log microhabitats.

Declines in riparian, wetland, old forest macrohabitats, and woody debris microhabitat accounted for the decreasing habitat incurred by the bird species tallied. About 45 percent of birds in the assessment area are associated with wetlands and riparian habitats, which declined in quantity (by conversion to other uses such as agriculture) and quality (through degradation from some management practices) over the historical period. A relatively large number of bird species (14%), compared with other vertebrate taxonomic classes, were associated with late-successional forest conditions, especially old forest (3.5%).

In contrast, most mammals were forest or range generalists (58%), which explains why for nearly 60 percent of the mammal species there was little estimated change in habitat area. Losses in mammal habitat appeared to be associated with conversion of rangelands to agriculture and loss of some old-forest macrohabitat and woody debris microhabitat.

Reptiles are mostly associated with rangelands (about 75%) and appeared to have lost habitat largely from the conversion of rangelands to agriculture, and conversion of native shrublands to exotic grasses. Although amphibians are primarily associated with aquatic and riparian habitats (52%), many species are not affected by the scale of disturbance from management practices as they affect terrestrial habitats, are fairly general in use of adjacent terrestrial habitats, or are affected by other factors.

Although percent change in current period habitat area for given species from historical area can be great, the absolute area affected might be very small and relatively insignificant within an individual landscape or Ecological Reporting Unit (ERU). The most dynamic ERUs, in terms of the number of species showing large shifts in habitat area as a percentage of the ERU area, were the Columbia Plateau, Northern Cascades, Northern Glaciated Mountains, Southern Cascades, and Upper Clark Fork ERUs (fig. 5.4; also see TS 1995). About 16 percent of the species in these ERUs were estimated to have lost habitat across greater than 10 percent of the ERU area, whereas similar increases in habitat were estimated for 15 to 20 percent of the species. With the exception of the Columbia Plateau, which is largely non-forest, habitat changes in these ERUs were driven primarily by changes in forest composition and structure. Changes of habitat area in the Columbia Plateau were largely from loss of rangeland habitats and gains in agricultural habitats.

Caution should be used in interpreting estimated habitat changes within ERUs, however, because changes for each species in each ERU were not individually evaluated by panel experts. Therefore, ERU-specific habitat trends should be considered working hypotheses. The Basin-wide model trends for each species are more reliable, but they do not provide ERU-specific results.

Implications of Broad-Scale Vegetation Changes for Species Using Native Grasslands

Nineteen percent (133 plant species) of the listed plant species and groups in the SER database are found in grassland structural stages of rangeland cover types (TS 1995) as well as in other structural

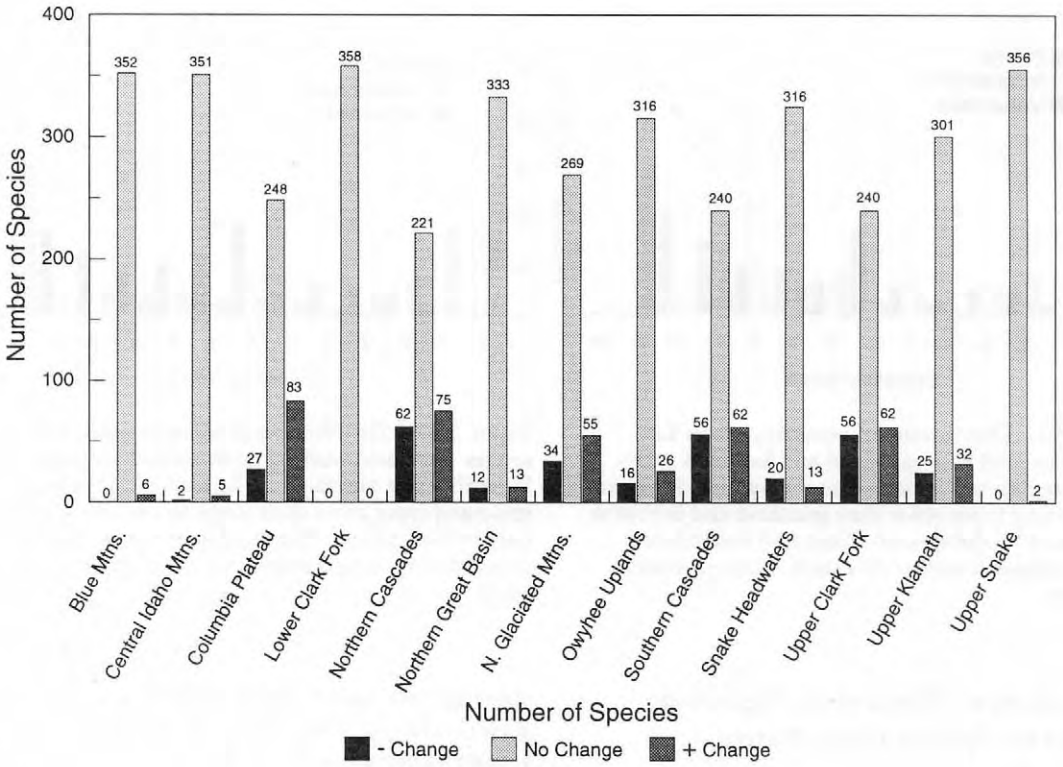

Figure 5.4— Trends in primary habitat change for vertebrates in ecological reporting units (ERUs) within the Basin since the early 1800s. No change was assessed as ±10% difference in habitat area over time relative to total ERU area, negative change was a >10% decrease relative to ERU area, and positive change was a >10% increase relative to ERU area. Primary habitat was estimated as the sum area of cover type/structural stage map polygons in ERU in which the species range intersected ≥10% of the ERU.

stages. [Plants in the database included only federally listed, candidate, or proposed listed species or groups, and are a relatively small subset (less than 10%) of the complete vascular flora.] Nearly 35 percent of species included in the assessment show low flexibility in their use of other structural stages, with versatility scores less than or equal to 2 (fig. 5.5). Versatility scores were calculated as the number of other structural stages used as primary habitat by the species, as listed in the SER database. Scores should be compared only within the vegetative communities, and not compared among vegetative communities.

Of the invertebrate species, 23 percent used herbaceous cover types among other cover types (TS 1995). Of those species, about one-third showed low versatility in using other than grassland/herb cover types and structural stages (fig. 5.5), whereas more than half showed fairly robust versatility by using more than nine other structural stages of other cover types. It is unknown if the entire entomofauna of the Basin would also display these trends. Only a small selection of invertebrate species representing different cover types and ecosystem functions were listed in the database.

Forty-seven percent of the vertebrate species used grassland/herb cover types (TS 1995). Most of those species showed relatively high versatility in habitat use (that is, few were linked solely to grassland/herb types). Low versatility was found in the nine percent of species that used less than or equal to other structural stages of range or forest cover types (fig. 5.5).

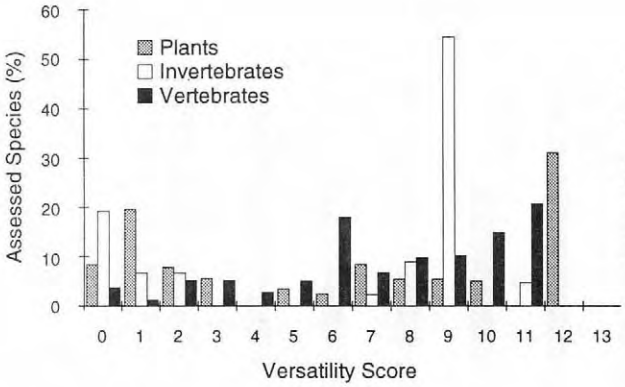

Figure 5.5— Distribution of versatility scores for species associated with grassland and herbland structure. Versatility was measured as the number of vegetation structural types other than grassland and herbland that are used by the species. Plant and invertebrate species considered were only a small subset of much larger biota.

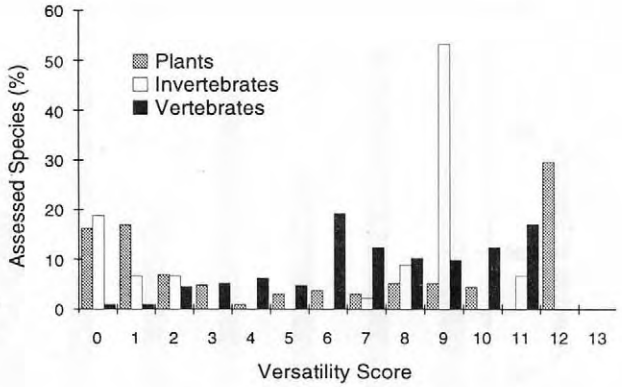

Figure 5.6— Distribution of versatility scores for species associated with range shrubland structure. Versatility was measured as the number of vegetation structural types other than range shrubland that are used by the species. Plant and invertebrate species considered were only a small subset of much larger biota.

Implications of Broad-scale Vegetation Changes for Species Using Native Shrublands

Twenty-three percent of the plant species or groups included in the SER database are found in rangeland shrub cover types or structural stages (TS 1995). Of those species or groups, 43 percent showed low versatility (scores less than or equal to 2) in using other habitats and consequent high impacts from habitat loss (fig. 5.6). However, 33 percent of those species using shrubland showed flexibility in habitat relationships with a high score of versatility (12).

Analysis of invertebrates in shrublands yielded results nearly identical to that for invertebrates in grasslands (TS 1995; fig. 5.6). This is explained by the fact that, as denoted in our SER database, invertebrate species are either rangeland generalists or species whose habitat relationships were not sufficiently well known to allow us to detect different use of grasslands or shrublands.

A relatively large percentage of the vertebrates (57%) use range shrublands (TS 1995), but few of those species were restricted in habitat use to shrublands (fig. 5.6). Only 5.5 percent of those species showed low flexibility (versatility score less than or equal to 2) in using other habitats, with over 80 percent showing use of greater than or equal to 6 other range or forest structural stages.

Implications of Broad-scale Vegetation Changes for Species Using Old Forests

About 15 percent (105) of the 686 vascular and nonvascular plant species or groups listed in the SER database are found in old forest habitats (TS 1995). However, vascular and nonvascular plant species or groups that use old forest have relatively high versatility with respect to the types of forest and range structural stages used. All species or groups are found in at least four structural stages other than old forest, and nearly 40 percent of the species use at least 12 other structural stages of various forest or rangeland vegetation types (fig. 5.7).

Among the 206 invertebrate taxa listed in the SER database and included in this analysis, 32 percent used old forest structural stages of early- and late-seral forests (TS 1995). Of those 66 species, 22

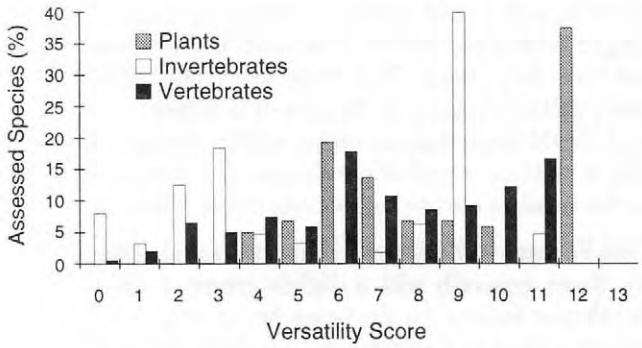

Figure 5.7— Distribution of versatility scores for species associated with old-forest structure. Versatility was measured as number of vegetation structural types other than old forest that are used by the species. Plant and invertebrate species considered were only a small subset of much larger biota.

percent used less than or equal to two other structural stages, showing relatively low versatility with respect to structural stages used (fig. 5.7).

About 60 percent (267 species) of all vertebrate species (467) in the Basin use old forests, along with other stages of forest development (TS 1995). Two percent (6 species) of those species had versatility scores less than or equal to one, and another 6 percent (17 species) used no more than two other structural stages (fig. 5.7). A separate expert panel analysis also found that 2 percent of all vertebrates were closely associated with the old forests to the exclusion of other stages, and an additional 13 percent were closely associated with mid- and late-seral stages of forest development.

Discussion of Rankings and Habitat Fragmentation

Trends in habitat area, as analyzed above, are not meant to necessarily imply trends in population sizes for individual species. Although it is true that appropriate habitat is essential for species to persist, populations respond to more than just habitat. Thus, this analysis should be considered only as a first approximation or a working hypothesis of potential trends of populations; species-specific trends might need further and more detailed analysis.

Broad-scale pattern analysis in the landscape assessment indicated that some of the relatively less abundant habitats have become spatially fragmented (see Landscape Dynamics chapter), thus compounding the potentially deleterious effects of overall habitat loss on regional viability of associated species. Native grasslands and sage-shrub habitats have become the most fragmented vegetation types in the Basin, largely from agricultural development. Lower montane ponderosa pine forests also showed substantial decreases in abundance and patch sizes, thus increasing fragmentation. Among the vertebrate "decreaser" species using old forests were the primary cavity-excavating woodpeckers, which provide cavities and inner-tree access for a wide variety of other fungi, plant, and animal species.

Vertebrate species with large home ranges often are adversely affected by loss and fragmentation of habitats (Lehmkuhl and Ruggiero 1991). Among the species closely associated with mid- and late-seral forest, species with large home ranges will be most affected by the loss and fragmentation of late-seral forests. About 50 percent of those species associated with mid- and late-seral forests have very small home ranges [less than 5 hectares (ha)] and may be less affected locally by fragmentation than would species with larger home ranges (greater than or equal to 5 ha). Thirty-two percent of the mid- to late-seral species have medium to large home ranges (greater than 1 km^2) and likely would be affected by habitat fragmentation locally and regionally. Effects of habitat fragmentation on viability of smaller-ranging species, however, may be accelerated if local habitat fragments become too small to support local, mostly isolated, genetically diverse populations of these species.

When considering the entire Basin, some forests have remained relatively intact, have increased in area, or have become more homogeneous or less fragmented as compared with conditions in early historic times (see Landscape Dynamics chapter). Montane forests have become slightly more homogeneous since early historic times. Upland juniper woodlands have increased in total area, increased

in average patch size, and decreased in isolation (distance between) patches. At least some species associated with montane forests and upland juniper woodlands will likely have increased their distribution.

Modeling of Mid-scale Habitat Patch Trends

Forest Mid-to-Old Structural Stages—Mid-to-old habitat (as identified by running the habitat patch model) within lower montane forests declined for vertebrates in all home range classes in nearly all ERUs (table 5.13). Species habitat area decreased with increasing home range area from an 11 percent decrease (median decline from historic level among ERUs) for species with small home ranges (less than or equal to 50 ha) to 21 percent decrease for species with the largest home ranges. The trend in a decreasing habitat area with larger home-range size among ERUs was driven by differences, between the Southern Cascades and the Upper Klamath ERUs, in habitat change among home-range size categories. Habitat for small home-range species in the Upper Klamath declined about 8 percent, whereas habitat for the largest home-range species declined 35 percent. The Southern Cascades ERU was the only ERU that showed an increase in lower-montane habitat from the historical period. Overall, lower-montane mid-old forest habitat not only declined, but forest fragmentation accentuated habitat loss for species with large home ranges.

In contrast to lower-montane forest habitat, montane mid-to-old forest habitat increased an average of 5 percent among all home range size classes for the whole Basin (table 5.13), but with high variability among ERUs. The area of effective habitat differed little among home-range classes, which suggests a uniform increase in montane forest habitat across landscapes. Major increases (greater than 70%) in montane mid-to-old forest habitat occurred in the Lower Clark Fork and Upper Snake ERUs, with other large increases (15 to 60%) occurring in the Blue Mountains, Central Idaho Mountains, and Columbia Plateau. In contrast, mid-to-old montane habitat decreases ranged from 3 percent to 24 percent in the Southern Cascades, Upper Clark Fork, and Upper Klamath ERUs. Changes in the area of subalpine mid-to-old forest habitat varied widely among ERUs, with an overall slight decline of 4 percent in the smallest home range classes (table 5.13).

Old Forest— Old forest habitat decreased across the Basin, generally with a slightly greater decrease in effective habitat for the larger home range species groups in montane and subalpine community types (table 5.14). Lower-montane old-forest structure declined among ERUs an average 26 percent for species with home ranges up to 300 hectares. The decline in habitat was much less for old-forest species with the largest home ranges (301-650 ha), which would indicate that forest fragmentation occurred at a scale smaller than 300 hectares. However, not all ERUs followed this trend. In some ERUs, (for example, Upper Klamath and Northern Cascades ERUs) habitat area changed similarly across home-range categories. In the Southern Cascades ERU, habitat area increased with increasing home-range size classes, whereas in the Northern Glaciated Mountains ERU no clear trend of habitat area across the home-range size classes emerged.

Montane and subalpine old-forest habitats declined consistently across the Basin. Habitat for species in the 301- to 650-hectare home-range group showed slightly greater decreases than for smaller home ranges, suggesting greater large-scale fragmentation effects. A prominent exception was the large increase (greater than 200%) in subalpine old-forest habitat in the Southern Cascades ERU, especially for species in the 650-hectare home-range size group.

General Species Trends

Much of the above discussions has focused on species response to habitats affected by management activities, particularly timber management and livestock grazing (also see Landscape Dynamics chapter). Here, we summarize some general

patterns among taxa and selected ecological subsystems, ecological processes, and other management activities. Although the following discussions pertain to the entire Basin, the information also can be separated by vegetative community and physiographic province.

This section summarizes information found mostly in the SER database and listed as key environmental correlates or KECs (appendix 5F). It is important to remember that, at this time, this information is very incomplete for plants and invertebrates. Because of the large scope of the current assessment, information on KECs for plant species and plant groups was gathered only for those species currently listed as C1 or C2 candidate, or for species and groups which the plant expert panels and contractors deemed deserving of additional conservation focus, that is, as potential C1 or C2 candidates. Thus, the plant information cited below is restricted to rare plants only. The information on invertebrates is also an incomplete representation of all invertebrates in the Basin. The database contains only example species of a much larger invertebrate fauna (see table 5.3). For plants and invertebrates, then, having species listed with key ecological correlates does not imply that those are the only such species with those correlates. Listings below of species must be viewed merely as examples until a more complete database can be compiled. It is a starting point for considering species in a much broader context.

No listing of recently extinct or extirpated taxa is available for plants, invertebrates, or vertebrates in the Basin. None of the information gathered for this assessment indicated that any vertebrate species has become extinct throughout their range in the Basin in recent decades. However, it is possible that undescribed, locally endemic species or subspecies might have vanished before they could be studied. The lack of evidence for Basin-wide extinction does not imply that extirpation at a local scale has not occurred. Local extirpations of some plant, invertebrate, and vertebrate species have occurred, caused either by natural disturbance or by human settlement and land use.

The status of isolated populations of some of the smaller-bodied, less vagile species may be precarious, and this deserves empirical study. Two possible examples are: the locally endemic potholes meadow vole (*Microtus pennsylvanicus kincaidi*), found only in one tiny location in central Washington at the edge of the otherwise extensive range of the parent species *M. pennsylvanicus*; and the locally endemic White Salmon pocket gopher (*Thomomys talpoides limosus*, which is also a federally listed C2 candidate taxon), also found at the edge of the range of its parent species, *T. talpoides*, in the Columbia Gorge (map 5.1a, 5.1b). These examples illustrate that sometimes the periphery of ranges provides conditions for differentiation of taxonomic lineages, in that distinct subspecies have evolved at these two species' ranges within the Basin. Thus, the periphery of species' ranges deserve conservation attention if the intent of management is to provide for evolutionary potential of the species. Other examples of potentially precarious, locally distributed organisms include locally isolated populations of species with disjunct ranges (maps 5.2a, and 5.2b, show some of the less widely-vagile amphibians and reptiles that have disjunct local populations within the Basin).

Species Associated with Forest Canopy Conditions

Hundreds, if not thousands, of species inhabit the forest canopy subsystem. However, a smaller set of species were identified that particularly correlate with canopy factors such as the density of live tree crowns and canopy closure (from queries to the SER database). Seven example invertebrates correlate with either open or closed canopies or tree crowns (three species of *Choristoneura*, *Malacosoma disstria*, *Scolytus ventralis*, *Pterostichus protractus*, and *Enoclerus sphegeus*). (These are examples only of invertebrate species associated with forest canopy conditions.) Among vertebrates, at least one amphibian (Coeur d'Alene salamander

Table 5.13— Past and current habitat area for vertebrates closely associated with mid- to late-seral (old forest) structural stages of forest development in the Basin. Species were grouped by home range area. Area was determined by the HABSCAPES pattern analysis procedure (Mellen and others 1995a).

however, some errors may remain.

Map 5.1a— Ranges of two locally endemic subspecies on the edges of their parent species' ranges. Potholes meadow vole *(Microtus pennsylvanicus kincaidi)* and its parent species, meadow vole (*M. pennsylvanicus*).

Map 5.1b— Ranges of two locally endemic subspecies on the edges of their parent species' ranges. White Salmon pocket gopher (*Thomomys talpoides limosus*) and its parent species, northern pocket gopher (*Thomomys talpoides*).

Map 5.2a—Examples of vertebrate species with disjunct ranges within and adjacent to the Basin: Woodhouse's toad, green frog and Northern bobwhite.

Map 5.2b—Examples of vertebrate species with disjunct ranges within and adjacent to the Basin: California mountain kingsnake, ground snake, longnose snake, and wild turkey.

Plethodon idahoensis), no reptiles, 12 birds (including 5 raptors, 4 primary cavity excavators, and others), and 3 mammals (American marten, heather vole *Phenacomys intermedius*, and woodland caribou) show particular correlations to canopy condition.

Other species show correlations with other forest stand characteristics, including tree bark structure, tree diameter (dbh), stem density, and flora. Certainly, many species can be included in these lists, but the species listed above provide a beginning point for identifying good indicators of changes in canopy conditions.

Species Associated with Mistletoe Brooms

A set of species show correlations with mistletoe brooms in tree crowns, including at least one invertebrate, the gossamer-winged butterfly *Mitowra johnsoni* (Lycaenidae). Among vertebrates, the marbled murrelet, spruce grouse (*Dendragapus canadensis*), Cooper's hawk (*Accipiter cooperii*), long-eared owl (*Asio otus*), and American fisher (*Martes pennanti*) all use mistletoe brooms for a variety of purposes.

Species Associated with Dead Parts of Live Trees

Among species associated with dead tree branches are the bark beetle *Scolytus ventralis* (Scolytidae), 6 species of woodpeckers, and 2 owls [great gray owl (*Strix nebulosa*) and, though it occurs erratically within the Basin, northern hawk owl (*Surnia ulula*)].

Species Associated with Trees With Exfoliating Bark

Some six vertebrates specialize on trees with exfoliating (peeling) bark: the white-headed woodpecker (*Picoides albolarvatus*), the brown creeper (*Certhia americana*), and four bats [silver-haired bat (*Lasionycteris noctivagans*), California myotis (*Myotis californicus*), little brown myotis (*Myotis lucifugus*), and Yuma myotis (*Myotis yumanensis*)], although some of these species also use other substrates as roost or nest sites.

Species Associated with Snags, Including Cavity-users

Another forest component is the presence of dead standing trees or snags. Primary cavity-excavator birds include some 17 species (3 chickadees, 3 nuthatches, and the rest woodpeckers). Beyond these 17 species are an additional 29 species of vertebrates that closely associate with snag substrates. These include 3 amphibians, 3 raptors, 7 bats, and 3 carnivores, which use a variety of specific snag characteristics for a wide variety of purposes. At least another 14 species are obligate secondary cavity-users (see discussion below under the section Interspecies Relations).

Species Associated with Down Wood

Among the listed, candidate, or potential candidate species of plants, 46 fungi species, the decayed wood bryophyte group, and five lichen groups were identified in the database as associated with down wood. At least 11 invertebrate species were identified as examples of the several thousand species associated with down wood. Two examples are the checkered beetle, *Enoclerus sphegeus* (Cleridae), which uses both fresh down wood and also intact but older down wood; and the leafcutting bee *Osmia bruneri* (Megachilidae), which uses snags and stumps, but also uses down wood stems with abandoned beetle burrows. Additionally, 82 species of amphibians, reptiles, birds, and mammals show correlations with down wood.

Interestingly, our investigations uncovered a small set of species that seem, in part, to specialize on bark piles at the base of snags. These include at least the invertebrate *Pseudogarypus hesperus* (Psendogarypidae: Chernilldal), and two amphibians, the northwestern salamander *Ambystoma gracile* (which also uses down logs), and the Larch Mountain salamander *Plethodon larselli* (which uses bark piles especially in the driest season in sites that also have moist talus and low soil content).

Species Associated with Litter And Duff

Some example species listed in the SER database that are closely associated with litter and duff conditions include six species of fungi, the humus/duff bryophyte group, one lichen species and two lichen groups (nitrogen-fixing soil lichens, and rotten log and tree base lichens). The carib beetle *Pterostichus protractus* (Carabidae) associates with fallen woody material and litter, as well as with bases of herbaceous plants, rocks, and snags. Among vertebrates, at least four shrews, the shrew-mole, and three songbirds show close associations with litter and duff.

Species Associated with Fire Processes and Insect Outbreaks

Plant species show various responses to fire suppression, frequency, intensity, and seasonality (table 5.15). Response to fire by fungus, lichen, and bryophyte species generally is not known, and response by vertebrate species is not easily depicted.

Among the many invertebrates that respond in various ways to fire, three examples are the lace bug *Acalypta cooleyi* (Tingidae), which is adversely affected by prescribed (and unprescribed) range fires that burn mosses; bark beetles including *Dendroctonus pseudotsugae* (Scolytidae), which are positively correlated with forest fire intensity and that associate with forest stands with severe drought (but not with forest stands with few to no fire-injured Douglas-fir trees greater than 30 cm dbh within a 10-km radius); and the thatch ant *Formica obscuripes* (Formicidae), which is positively correlated with fire frequency.

Among the vertebrates, western tanager (*Piranga ludoviciana*) and purple martin (*Progne subis*) respond positively to recent burns (tanagers more in cottonwood riparian forest, and martins in locations near water). Red-headed woodpecker *Melanerpes erythrocephalus* (rare in the Basin) and orange-crowned warbler (*Vermivora celata*) respond more to older burns, the woodpecker in cottonwood/oak forests and open woodlands, and the warbler more in brushland, riparian, and fire-generated shrubby montane sites with deciduous trees in the understory. Lewis' (*Melanerpes lewis*), black-backed (*Picoides arcticus*), and three-toed (*Picoides tridactylus*) woodpeckers, along with mountain and western bluebirds (*Sialia currucoides* and *Sialia mexicana*), associate with sites where fires have killed the forest overstory.

Black-backed and three-toed woodpeckers associate with mid- to high-elevation forests following irruptions of insect populations such as bark beetles. In the eastern portion of the Basin, the uncommon Tennessee warbler (*Vermivora peregrina*) increases after outbreaks of spruce budworm.

Species associated with Recreation Activities, Roads, and Trails

As with all other management activities, ground and soil disturbances associated with recreational areas, roads, and trails, can have positive, neutral, and negative effects on distribution or abundance of species. Among vertebrates, black-tailed deer may be negatively affected by the presence of cross-country skiers, destination resorts, logging activities, off-road vehicle activity, roads, and subdivisions. Other species also adversely affected by such disturbance activities include tailed frog (*Ascaphus truei*), western toad (*Bufo boreas*), Woodhouse's toad (*Bufo woodhousii*), Great Basin spadefoot, Coeur d'Alene salamander, sage grouse, and mountain goat.

Vertebrates benefiting from disturbance activities are species associated with building structures, including swallows and some of the bats (such as pallid bat *Antrozous pallidus*); gravel road and shoreline substrates, benefiting species such as killdeer; agricultural areas, benefiting species such as horned lark *(Eremophila alpestris)* and rosy finches (*Leucosticte* spp.); and human presence and habitations, benefiting species such as house sparrow (*Passer domesticus*), opossum, house mouse (*Mus musculus)*, and black rat (*Rattus rattus*).

Table 5.15— Plant species associated with various aspects of fire dynamics (excluding fungi). BG = bryophyte group, L = lichen, LG = lichen group, P = vascular plant, PG = vascular plant group (source: SER database).

Human activities that result in carrion (fresh dead animals) might benefit the set of carrion-feeding species including turkey vulture (*Cathartes aura*), bald eagle, gray jay (*Perisoreus canadensis*), common raven (*Corvus corax*), American crow (*Corvus brachyrhynchos*), wolverine, and coyote, depending on type and location of the carrion.

Key Ecological Functions of Species

This discussion presents findings on species' key ecological functions associated with the major terrestrial ecological subsystems of the Basin (table 5.16). The major ecological functions we addressed were: species that predominate in the biomass of ecosystems; herbivory; nutrient cycling relations; interspecies relations; soil productivity; wood decomposition; and water quality. Understanding and maintaining ecological functions, including nutrient cycling and fire relations, are critical facets of maintaining ecosystem health for inland Northwest ecosystems (DellaSala and others 1995). Identifying such ecological functional groups of species may be more useful for management of Federal lands in the Basin than would attempting to identify individual keystone species.

This section summarizes information derived from the SER database under key ecological functions (KEFs). Information on species' KEFs is incomplete, particularly for plants and invertebrates. Information on KEFs for plant species and plant groups was gathered only for those species currently listed as C1 or C2 candidates or for species and groups which the plant expert panels and contractors deemed deserving of additional conservation focus, that is, potential C1 or C2 candidates. The plant information cited below is typically for plants that are scarce; other plant species with particular functions are not discussed here. The information on invertebrates is also an incomplete representation of that fauna as the database contains only example species of a much larger invertebrate fauna. Our intent was to outline some of the major categories of species functions within the Basin rather than to list exhaustively all species with each ecological function.

Major Biomass

Species that predominate in or affect the biomass of an ecosystem can have a major controlling function in storage and flow of nutrients and energy through the trophic levels. Many species, including plants, can dominate as major biomass of various environments. Among invertebrates, soils can be dominated numerically by mites, springtails, and other species. Western spruce budworm (*Choristoneura occidentalis*) and Douglas-fir tussock moth (*Orgyia pseudotsugata*) can greatly affect production of major biomass, as they are key to carbon and nutrient recycling, plant biomass turnover, soil productivity, and energy flow dynamics in some forest ecosystems.

In litter and duff layers of many forests, amphibians often comprise either a major biomass component or at least serve to mediate energy flow through trophic levels. This may be surprising to those who would guess that only the larger or more visible vertebrates perform this function. Specifically, throughout the Basin, at least nine salamander species and three frogs act as key energy gates or major biomass components. Collectively, these amphibians are most sensitive to changes in down wood, litter, and duff depths and characteristics; still and flowing water quality and quantity; and precipitation quality and weather patterns. Thus, manipulating these components through management activities can influence the distribution and abundance of associated amphibians and thus their ecological functions.

Herbivory

Herbivory functions of invertebrates were discussed earlier. In summary, at least one example species of tree bole feeder, five bark beetles, and 22 defoliators (including cankerworms, budworms, leaf beetles, miners, moths, shoot borers, sawflies, and others) can serve to alter plant succession, create new vegetative conditions for other wildlife, decrease primary production of host plants, and impose other changes on vegetation substrates and ecological processes of their host environments.

Table 5.16— A simple classification of ecological subsystems found in the Basin.

1. Terrestrial Above-Ground Environments
    (a) Upland terrestrial conditions - forests
        Tree canopy, subcanopy
        Shrub layer
        Grass/forb layer
    (b) Upland terrestrial conditions - shrublands and grasslands
        Trees
        Shrubs
        Grass/forb layer
        Cryptogamic crusts (soil surface)
2. Terrestrial Below-Ground Environments
    (a) At- and below-surface zones: coarse wood, litter, duff
    (b) Soil (O, A Horizons)
    (c) Root sphere influence zones
3. Riparian influence zone
    Riparian shade, leaf litter, large wood
4. Aquatic systems
    (a) Lotic systems
        Stream size scale and gradient type
        Bank and channel stability; side slope angle and erosion potential
        Reach type; habitat characteristics and processes (edge effects,
            storage of organisms, hydrology, particle size sorting)
    (b) Lentic systems
        Water body size
        Water permanence
            lake or pond
            astatic lake or pond
            intermittent pond
            wet meadow, seep, bog, fen

Vertebrates with key herbivory functions include all the ungulates discussed previously, as well as at least five species of waterfowl (four geese and brant), sage grouse, at least three species of vole, and the black-tailed jackrabbit and other rabbits. All of these major herbivores are capable of altering plant community structure and plant species composition, particularly the ungulates as studied in the Blue Mountains by Irwin and others (1995). Even the voles can modify grassland structures.

Nutrient Cycling

Species with key roles in determining cycling rates of nutrients (for example, nitrogen, phosphorous, and carbon) include those involved in physical transfer of substances, nitrogen cycling, and carbon sequestration. First are species that particulary affect the physical transfer of substances for nutrient cycling. In turn, this key ecological function serves to support vegetation succession and to alter the composition and enhance the productivity of the environments. This function is performed by various animals including 21 example invertebrate

species among 13 families. Two examples are large aspen tortrix (*Choristoneura conflictana:* Tortricidae) and pandora moth (*Coloradia pandora*: Saturniidae). Many more invertebrates with this function occur within the assessment area. Vertebrates with this function number at least 32 species among 12 families; the species include 11 amphibians [two examples are Pacific chorus frog (*Pseudacris regilla*) and rough-skinned newt (*Taricha granulosa*)], one bird [Canada goose (*Branta canadensis*)] and 21 mammals [two examples are the bushy-tailed woodrat (*Neotoma cinerea*) and the little brown myotis (*Myotis lucifugus*)].

Second are species specifically affecting nitrogen cycling. These include nitrogen-fixers, nitrogen-immobilizers, and sources for nitrogen mineralization. Among the species listed in the SER database, 1 bryophyte group, 7 lichen groups, and 32 vascular plant species are mostly nitrogen-fixers. The dry soil bryophyte group harbors nitrogen-fixing bacteria and is found in all general soil categories. The seven nitrogen-fixing lichen groups include groups labelled in the SER database as excess nitrogen indicators and nitrogen-fixing groups of epiphytes, riparian and seepage species, rock and soil associates, and tundra sod builders. Rare vascular plants affecting nitrogen cycling, as listed in the SER database, include some 22 species of milk-vetch, as well as lupines, monkeyflower, crazyweeds, clovers, and others. (Additional leguminous and other vascular plants in the Basin also perform nitrogen fixation; these are not included in the SER database at this time).

Invertebrates and microorganisms with nitrogen relation functions include the competitive bacterium *Bacillus thermophilus*, the nitrogen-immobilizing bacterium *Klebsiella panticola*, and many rotifers. The bacterium serves to decompose labile and intermediate-labile carbon:nitrogen substrates and act as a source for nitrogen mineralization. The rotifers participate in nitrogen-retention in soil.

A third key function is carbon sequestration. Many trees and shrubs contribute to sequestration of atmospheric carbon, acting as part of a global buffer system involving cycling of carbon, in various forms, from atmosphere to vegetation to soils and back. Among the species listed in the SER database with this function are seven *Carex* (sedge) plant groups found in calcareous and noncalcareous peatlands; dry low-elevation meadow vegetation communities; and mesic and wet meadow vegetation communities at low, moderate, and alpine elevations. Carbon-cycling models (for example, Harmon and others 1990, Turner and others 1995) can help estimate the rate of contribution of forests to carbon stores.

Interspecies Relations

Every species interacts with others. However, several key interactions may be of interest to ecosystem management, including insectivory, pollination vectors, transport of plant disseminules, nest parasitism, cavity nesting, and burrow excavation. These interactions affect productivity, diversity, and structure of ecological communities.

Many insectivorous (that is, insect-feeding) vertebrates within the assessment area act as biocontrol agents. While these biocontrol organisms may not eliminate irruptive insect populations, they may play a significant role in reducing the amplitude of insect outbreaks. Insectivorous vertebrates with such biocontrol potential include an amphibian (tiger salamander *Ambystoma tigrinum*), 12 birds, and 9 mammals. Insectivorous birds include trumpeter swan (*Cygnus buccinator*), American kestrel (*Falco sparverius*), flammulated owl (*Otus flammeolus*), common nighthawk (*Chordeiles minor*), black-backed woodpecker (*Picoides arcticus*), barn swallow (*Hirundo rustica*), northern rough-winged swallow (*Stelgidopteryx serripennis*), mountain chickadee (*Parus gambeli*), mountain bluebird (*Sialia currucoides*), hermit thrush (*Catharus guttatus*), red crossbill (*Loxia curvirostra*), and evening grosbeak (*Coccothraustes vespertinus*). The mammals include deer mouse (*Peromyscus maniculatus*) and many bats.

This list of species could have important economic implications because some insectivorous species feed on insect pests. The evening grosbeak and mountain chickadees are primary feeders of spruce budworms. Red crossbill, associated with mature and old conifer forests, feeds on spruce budworm larvae. The silver-haired bat is a moth and beetle pest predator in forests. Common nighthawk, big brown bat (*Eptesicus fuscus*), and pale western (that is, Townsend's) big-eared bat (*Plecotus townsendii pallescens*) feed on insects in agricultural and urban environments. Black-backed woodpeckers feed on bark beetles, especially during outbreaks. Little empirical work has been done for most of these species to quantify rates of feeding and its specific effects on the amplitude of insect population outbreaks. Koplin (1969) suggested that black-backed woodpeckers can suppress the amplitude of bark beetle outbreaks. Takekawa (1984) evaluated the silvicultural economic advantage of providing for evening grosbeaks.

Another interspecies relation of potential interest to ecosystem management is pollination vectors. Pollination vectors are species which aid production of native fruit and seed-bearing plants that, in turn, feed mammals, birds, ants, and other insects. There is no master catalogue of such vectors for the Basin, but the SER database contains a sample of 63 invertebrate species (among 12 families) with this key function. Among vertebrates, at least five species of hummingbirds and one songbird [northern oriole (*Icterus galbula*)] act as angiosperm pollinators. The hummingbirds pollinate tubular flowers; the rufous hummingbird (*Selasphorus rufus*) in particular is co-evolved with red tubular flowers.

Another interspecies relation is dispersal of fungi, plants, plant parts, and invertebrates. At least 153 vertebrate species engage in transportation of seeds, spores, or other plant disseminules. Some of the vertebrate dispersers of fungi include southern and western red-backed voles (*Clethrionomys gapperi* and *Clethrionomys californicus*), pika (*Ochotona princeps*), flying squirrel (*Glaucomys sabrinus*), Columbian mouse (*Peromyscus keenii*), least chipmunk (*Tamias minimus*), Douglas' squirrel (*Tamiasciurus douglasii*), and Rocky Mountain elk. The western red-backed vole disperses nitrogen-fixing mycorrhizae. Douglas' squirrel and southern red-backed vole, and probably others, disperse lichens. Most of the waterbirds, including waterfowl, shorebirds, grebes, herons, and others, disperse aquatic plants, algae, and invertebrates.

The largest groups of vertebrate dispersal agents are those that disperse seeds and fruits (at least 85 identified vertebrate species) and those that disperse plants or non-seed or fruit plant parts (60 vertebrate species). The seed- or fruit-dispersers include a wide variety of aquatic and terrestrial birds and mammals, covering a wide range of environments within the Basin area. A few seem to be specialists. For example, Clark's nutcracker (*Nucifraga columbiana*) is a key element in regeneration of whitebark pine–which is declining in the Basin–as well as pinyon pine, by caching (that is, burying) seeds in the ground. White-headed woodpecker disperses ponderosa pine seeds and California ground squirrel (*Spermophilus beecheyi*) disperses oak (further west and south from the Basin, tanoak) acorns and seeds. Rodents, especially red-backed voles, play key roles in re-establishing trees by burying seeds and spreading spores of beneficial symbiotic fungi, especially after timber harvest or fires. However, some evidence suggests that if the clearing is too large, they will aid in re-establishment of trees only along the edge of forest cover (Mills 1995).[35]

Bird nest parasitism is a specialized breeding function of the brown-headed cowbird (*Molothrus ater*). At least 30 other bird species suffer as nest hosts to this species. Affected species include forest-inhabiting vireos, warblers, and sparrows; marshland blackbirds and yellowthroats; shrubland sparrows and flycatchers. To our knowledge, no study has determined the extent to which

[35] Also, personal communication. 1995. Allen E. Thomas, Fish and Wildlife Biologist. U.S. Department of Interior, Bureau of Land Management, Idaho State Office, 3380 Americana Terrace, Boise, Idaho 83706.

cowbird nest parasitism is a factor in declines in other bird species. Studies in the Sierra Nevada of California have suggested that there could be severe, negative affects on host species.

The 17 vertebrate species that function as primary cavity excavators in trees include 11 woodpeckers, 3 nuthatches, and 3 chickadees [chestnut-backed chickadee (*Parus rufescens*), included here, is an occasional primary cavity excavator]. Collectively, these species reside in a variety of pine, fir, and hardwood woodlands and forests in the assessment area.

At least another 14 species act as secondary cavity users, using natural tree cavities or cavities created by the primary excavators, for roosting or nesting. These include wood duck (buffleheads, mergansers, and a few other waterfowl may also serve this role), 5 small owls, 3 chickadees, 2 swallows, white-breasted nuthatch (*Sitta carolinensis*), ash-throated flycatcher (*Myiarchus cinerascens*), and common raccoon (*Procyon lotor*). Doubtless, other species can be added to this list.

Competition for cavities may be high in forest conditions lacking trees or snags of adequate dbh with cavities. Northern saw-whet owls (*Aegolius acadicus*) nest early in the season and thus may displace other later-nesting secondary cavity users. Likewise, boreal owls (*Aegolius funereus*) occupy larger tree cavities and nest earlier than many other secondary cavity users, and may displace flying squirrels. On the other hand, flammulated owls, our only neotropical migratory owl, are late nesters and may not find adequate nest sites if they are occupied by earlier nesting species. Northern pygmy-owls (*Glaucidium gnoma*) likely compete for cavities with passerines (songbirds). Western screech owls (*Otus kennicottii*) may actively usurp nests from squirrels and flickers. Among songbirds, violet-green swallows (*Tachycineta thalassina*) are an active competitor for nesting cavities.

As a parallel to the cavity-using species, another species set engages in primary burrow excavation in a variety of habitats and conditions. Among the invertebrates, this set includes a variety of bark beetles which create distinctive galleries of burrows in the tree cambium beneath the bark. Two other primary ground-burrowing invertebrates are the thatch ant *Formica obscuripes* (Formicidae), whose nests are home to many arthropod species and serve as wintering burrows for small mammals, and *Arctosa littoralis* (Lycosidae: Araneida), whose 15 to 25 centimeter deep burrows in sand, dug for diurnal hiding, might possibly influence the structure of sandy beach habitats. Many other burrowing invertebrates occur in the Basin.

The primary burrow-excavating vertebrates constitute about 41 taxa (38 species and two subspecies of northern pocket gopher listed individually in the SER database), which include 1 amphibian (Great Basin spadefoot), 3 birds [bank swallow (*Riparia riparia*), belted kingfisher (*Ceryle alcyon*), burrowing owl (*Athene cunicularia*)], and the rest mammals. Great basin spadefoot is a primary excavator in sandy soil and uses mammal burrows in other substrates. The mammals include mountain beaver (*Aplodontia rufa*), the rare pygmy rabbit (*Brachylagus idahoensis*), striped skunk (*Mephitis mephitis*), mink (*Mustela vison*), American badger (*Taxidea taxus*), 2 moles, 6 gophers, 14 squirrels or chipmunks, 7 mice or rats, and 2 foxes. The mountain beaver, skunk, badger, and foxes in particular dig large burrows used by a slightly different constellation of other species.

The secondary burrow-using species depend on the primary burrow excavators for their tunnels. This set includes at least 13 vertebrate species (3 amphibians, 3 reptiles, 1 bird, and 10 mammals): 2 salamanders and spadefoot; longnose leopard lizard, striped whipsnake, and gopher snake; burrowing owl; and Virginia opossum, striped skunk, 3 mustelids (ermine, long-tailed weasel, and mink), and northern grasshopper mouse. In particular, the longnose leopard lizard depends on rodent burrows (kangaroo rats, pocket mice) for cover. Striped whipsnake uses deep underground crevices in cold weather and is also a secondary user of mammal burrows for egg-laying.

Soil Productivity

Species with ecological functions affecting soil productivity include a variety of plants, invertebrates, and vertebrates in seven function categories: physical soil turnover, nitrogen retention or uptake, soil stabilization, rock weathering, detoxificaion of xenobiotics, metal accumulation, and vegetation succession. Soil productivity can be related to complex processes. For example, Seasted and Knapp (1993) reported that grassland ecosystem productivity can display "transient maxima," which are related to how grazing and fire affect water, nitrogen, and light availability.

In one sense, all plants die, decompose, and thus contribute to soil organic matter and composition. In particular, one bryophyte group (rock calcareous bryophytes), 2 plant groups (*Carex* ephemeral meadow low-moderate group and *Carex* subalpine groups), and 13 plant species, listed in the SER database, significantly contribute to soil formation and soil organic material, particularly in poorly developed or nutrient-poor soils and limestone or rock substrates. Many other species and plant groups not listed in the SER database also contribute to this function.

Some 51 example invertebrate species or subspecies distributed over seven families are included in the database as examples of invertebrates that recycle soil layers and nutrients, and influence soil structure, porosity, and aggregation by their physical digging actions. Among vertebrates that perform this function are a number of fossorial mammals listed above as primary burrow excavators. In particular, western and Woodhouse's toads, broad-footed and coast moles (*Scapanus latimanus* and *Scapanus orarius*), shrew-mole *(Neurotrichus gibbsii)*, 4 ground squirrels, white-tailed antelope squirrel (*Ammospermophilus leucurus*), and water vole (*Microtus richardsoni*) significantly contribute to soil aeration and affect soil structure. The water vole contributes to soil aeration and drainage of wet soils.

Bacteria, nematodes, rotifers, and protozoa play critical roles in nitrogen retention or uptake in soils. Groups of competitive rhizosphere (root sphere) bacteria, bacterial pathogens, and beneficial bacteria, are responsible for nitrogen retention and mineralization in soils. Bacteria-feeding nematodes (*Acrobeloides* spp.) engage in mineralization of nitrogen immobilized in bacterial biomass, and may be responsible for up to 40 percent of plant available nitrogen. Rotifers (virtually unstudied in the assessment area) and the bacterial-predator protozoa such as *Amoeba amoeba* also engage in mineralization of nitrogen immobilized in bacterial biomass, and may be responsible for up to 50 percent or more of plant-available nitrogen in some agricultural systems. In addition, saprophytic fungi enter the process, as most plant-available nitrogen must cycle through soil fungal biomass in forest soils.

Many plants contribute to soil stabilization, including 6 bryophyte groups, 9 lichen groups, 22 plant groups, and at least 1 recognized lichen species and, among the rare plants listed in the SER database, 76 plant species or subspecies. The specific functions performed by this diverse group include: trapping of sediments (for example, aquatic submerged bryophytes, wet rock bryophytes, and wet soil bryophytes); reducing wind erosion (for example, dry soil bryophytes); colonization of harsh sites or erodible slopes; and stabilization of stream banks and soils during flood events (for example, *Artemesia* spp., the *Carex* rocky streambed species group, the *Mimulus guttatus* species complex and *Mimulus* high-elevation wet-habitat species group, and the *Penstemon* foothills to montane meadow species group). Species that stabilize soils on post-fire sites include several species of milk-vetch (*Astragalus* spp., *Chaenactis cusickii*, *Penstemon peckii*, and others; also see table 5.15). Many other plants not listed in the SER database likely perform this function more widely throughout the Basin. The beneficial bacteria *Microcoleus* also serve to stabilize soil and prevent erosion.

Lichens excel as soil stabilizers, with 11 lichen species groups occurring in a wide array of environments serving to weather rock substrates. Additionally, seven vascular plant species in the

SER database, including penstemons, a rockmat, an ivesia, and a phacelia, also perform this service. Rock weathering is often a prelude to further soil formation and provides a substrate for other colonizers needing mineral soils.

The ectomycorrhizal mat-forming fungi *Hysterangium* may detoxify some types of pesticides, herbicides, and pollutants. The vesicular fungus *Glomus mossae* and the ectomycorrhizal mat-forming fungus *Hysterangium* may sequester heavy metals in fungal hyphae, preventing heavy metals from damaging or killing plants.

By definition, vegetation succession proceeds by new plant species invading a site. Many plant species of the Basin are colonizers. Some bacteria groups, exemplified by the bacterium *Rhizobium melliotii* and the beneficial bacteria group *Microcoleus*, aid preparation of the soil for succession by nitrogen-fixation.

Wood Decomposition

Wood decomposition is a highly complex process that can involve several thousand species of bacteria, microfungi, macrofungi, nonvascular and vascular plants, invertebrates, and vertebrates. A single down log can undergo decay succession; many species are present only at specific wood decay stages. One invertebrate in particular, the carpenter ant *Camponotus modoc* aids in decomposition of standing and down wood. It operates at the hub of a complex ecological process involving insectivorous predatory birds, primary and secondary cavity nesters, and defoliators. Partially decomposed standing wood provides nest, feeding, and roost sites for many other species (see above, under species associated with snags, dead parts of live trees, and exfoliating bark); decomposing down wood is also used by a variety of other species (see above, under species associated with down wood and litter and duff).

Among vertebrates that might aid wood decomposition are the rubber boa (*Charina bottae*) and sharptail snake (*Contia tenuis*), which excavate rotten logs for cover and prey; the pileated woodpecker (feeds more frequently on large down logs compared to other woodpeckers) which breaks logs apart while foraging for insects and larvae; and the black bear and grizzly bear, which may contribute to soil nutrient cycling by breaking logs apart in search of food.

Bioindicators of Water Quality

Algae and aquatic invertebrate species can act as bioindicators of water quality. Pond- and lake-dwelling high country salamanders and frogs also are sensitive indicators of acid precipitation and changes in water quality. The tailed frog is sensitive to, and is probably a very good indicator of, increases in temperature and sedimentation in mountain streams. Additionally, some 19 species of shorebirds, including sandpipers, yellowlegs, plovers, and others, probably are good indicators of pollution of inland nesting and stopover sites.

Identifying Keystone Species

The term keystone has been used in the ecological literature to refer to species whose functions directly or indirectly affect the presence and abundance of many other species. Keystones can be plants and allies, invertebrates, or vertebrates. The above reviews demonstrate that species assemblages can be identified as those closely associated with specific environmental substrates or with ecological functions. Collectively, all such species are "keystone" in that they, as a group, define the structures and processes of ecosystems.

At our present knowledge level, few species can be demonstrated as being individually "keystone" in that their removal from the ecosystem would greatly diminish the diversity and functions of the system. Further, Mills and others (1993) argued that the concept of keystone species is wrought with ambiguity and imprecision, and that land managers instead should explicitly consider the complexity of interactions in natural systems. Following their suggestion, we have not identified a small set of species as keystones or "indicators."

One problem with the use of the indicator species concept on Federal land management has been described as, "the problem of objectively defining which species are keystones makes it likely that subjectively chosen subsets of species will be so labeled, whereas other species of similar importance will be ignored" (Mills and others 1993).

We use the term "key environmental correlates" (KEC) here to connote the major environmental requirements of a species. A given KEC, such as cliffs, can have many associated species, and a given species can have many KECs. Thus, if a management objective is to maintain the full set of species in an area, we recommend, along with Mills and others (1993), that the full set of KECs of all species be provided rather than arbitrarily focusing on only a few species and KECs.

We classified KECs and KEFs into two hierarchies of categories (appendices 5F, 5G). In these hierarchies, each KEC and KEF category is given a unique code and can be related to species in several levels of specificity in the SER database. For example, all species with KECs including the general category of non-vegetation terrestrial substrates (KEC level 3, appendix 5F) can be identified. A subset of these species would be those associated much more specifically with lithic (rock) substrates (KEC level 3.3). And then, a subset of that subset of species would be those associated much more specifically with cliffs (KEC level 3.3.3). In this manner, general as well as specific associations of species with environmental and habitat conditions can be depicted. The hierarchy of key ecological functions of species (KEFs, appendix 5G) operates the same way. Ultimately, then, it is the full set of all species and their environmental correlates and ecological functions that can be depicted in the SER database and that collectively define biotic processess and biodiversity of ecosystems.

Use of Ecologically Functional Equivalents

Do species with the same categories of key ecological functions perform the same ecological service? In a broad sense, by definition of functional categories, yes. For example, black-tailed jackrabbit (*Lepus californicus*), meadow vole (*Microtus pennsylvanicus*), greater white-fronted goose (*Anser albifrons*), and Ross' goose (*Chen rossii*) all perform functions of herbivory (that is, all are herbivores) (maps 5.3a, 5.3b). However, each species in the above list performs its function under different sets of environmental conditions and geographic areas (maps 5.3a, 5.3b) using different behaviors and affecting their food sources in different ways. Ultimately, each species is unique in its set of behaviors, distribution, and functions, so that no two species are exactly interchangeable. Thus, we do not suggest viewing species with common, general ecological functions such as herbivory as equivalent and mutually replaceable in management objectives.

Endemism, Biodiversity, and Natural Areas

With major contributions from expert panels, we mapped centers of concentration of (1) species rarity and endemism and (2) high biodiversity. We defined centers of concentration of species rarity and endemism as locations with unusually high numbers of species that are rare or that are locally or regionally endemic. We defined centers of concentration of high biodiversity as locations with unusally high numbers of species of all abundance classes and all types of geographic distributions. Within this framework, the expert panels identified centers of concentration variously based on high species richness, high landscape diversity, uniqueness of species communities, or high density of rare plant occurrences. Many of the high biodiversity centers of concentration, especially in the plant panels, were the same as the centers of many rare and endemic species as initially defined by the plant expert panels.

All panels identified centers of rarity and endemism in the southwestern Oregon portion of the Basin (Southern Cascades, Upper Klamath, and Northern Great Basin ERUs), along the Snake River (Owyhee Uplands ERU), the Columbia River Gorge (including the Northern Cascades

Map 5.3a— Vertebrate species with the key ecological function of herbivory: Meadow vole and blacktailed jackrabbit.

Map 5.3b—Vertebrate species with the key ecological function of herbivory: Greater white-fronted goose and Ross' goose.

ERU) and the desert steppe in central and southern Washington (Columbia Plateau ERU) (table 5.17). Centers of rarity and endemism of plants and animals occurred in nearly all major landforms.

The centers of concentration of rarity and endemism seemed to pertain to taxonomic groups with low mobility. This may be because species with low mobility may be more apt to develop endemic forms adapted to local conditions. Centers of concentration of rarity and endemism were mapped based on distributions of species of vascular plants, reptiles, amphibians, and fish. Invertebrates were mapped only to family level due to lack of research on species taxonomy and field ecology. Few nonvascular plant species were identified in this mapping exercise due to lack of field studies. Small mammals species were included in the mapping, but large mammals were not because their larger home ranges generally precluded identifying specific sites as centers of concentration. Panelists did not identify centers of concentration of rarity and endemism for birds and bats because of the high mobility of these species. Instead, correlations between species and habitat for birds and bats were identified (SER database; TS 1995).

We also listed the species associated with the centers of concentration and commented on each area and possible causes for local conditions. For example, we identified when an unusual soil type, geological formation, management activity or condition appeared to contribute to the rarity or endemism of associated species. This documentation was provided in a geographically referenced database linked to individual centers. Some of the factors contributing to rarity and endemism were: thermal hot springs, alkali pools, high topographic relief that served to isolate mountain tops or canyons, agricultural activities, springs, seeps, wetlands, and riparian habitats.

Disturbance regimes likely play a role in maintaining biodiversity of some centers of concentration, although more remains to be learned of such relations. Huston (1994), among others, hypothesized that relatively high biodiversity can be maintained with disturbances that reduce or eliminate dominant species. Such disturbances can include biotic factors such as predation, herbivory, parasitism, disease, and complete emigration of a dominant competitor, or abiotic factors such as floods, fires, severe windstorms, and extreme weather.

The centers of concentration of high biodiversity or high occurrences of plants and aquatic species were more dispersed across the Basin than were the centers of concentration of species rarity and endemism, but they corresponded well to large blocks of natural areas. This may be because the large natural areas and roadless areas receive less human disturbances and are more likely to provide conditions for the full set of naturally-occurring species. Two notable exceptions were the large wilderness blocks in central Idaho and the east Cascades in Oregon, which contained few centers of high biodiversity.

Centers of concentration were mapped separately for taxonomic groups of plants and animals. When overlayed, locations with three or more centers defined smaller "hot spots" of rarity and endemism, and high biodiversity, for plants and animals combined. We identified 12 hot spots of rarity and endemism (table 5.17, map 5.4) and 7 hot spots of high biodiversity within the Basin (table 5.18, map 5.4). Doubtless, additional hot spots may be identified at finer scales and levels of geographic resolution than we used in this project. Collectively, these hot spots mainly occurred in the northern glaciated and unglaciated mountains, central and southern Cascade mountains, Washington and Oregon plateau country, Great Basin plains, and the Snake River valley (maps 5.4, 5.5).

The plant and amphibian/reptile panels were the only panels that identified areas of high biodiversity or high plant occurrences. The biodiversity map themes and the rarity/endemism map themes were developed using different sets of criteria among the panels, for reasons explained above. This approach provides a starting assessment for further exploration of hot spots and their relation to species distributions.

Table 5.17—Hot spots of species rarity and endemism[1] (see map 5.4 for location of numbered areas).

Number[2]	Description/Location	Natural Area[3]	Road Density[4]	Human Density[5]	Vegetation	Ownership
RE1	Washington: Columbia Basin shrub - steppe, Vantage, Washington area and Saddle Mtns. High degree of disturbance around the area due to agriculture and grazing. Remnant steppe areas rare, populations limited.	Hanford RNA	Mod., some low	Mostly low - very low	Desert salt shrub, basin sagebrush, mountain big sagebrush	Almost all private, small BLM, no FS
RE2	Washington/Oregon: Columbia River Gorge, both sides, from Cascade Locks to east of Biggs, north to Yakama Reservation, west outside project boundary. Rapid elevation changes, climatic contrasts. Gorge and river are corridors but highway and cliffs can be barriers.	Small: TNC reserve; SIA; Wilderness	High to west; mod.-low north, south, and east	About 1/3 in high density, rest in low	Mixed, contrast: fir, hemlock, cedar to west; ponderosa pine, mountain big sagebrush and agricultural, grass-lands north, south, and east.	Most private, 2 National Forests; no BLM; National Recreation Area in Gorge
RE3	Oregon: Crest of Umatilla Mtns., elevational changes. Many westside species are isolated and disjunct on mountain tops. Seeps, riparian and springs important. Diverse, mosaic.	About 1/3 wilderness; 1 RNA; 1 TNC reserve	Mod-high outside wilderness, none within	Low-very low	Grand fir, interior ponderosa pine, subalpine herb, lodgepole pine, spruce/fir	All Umatilla National Forest, no BLM
RE4	Oregon: Wallowa Mtn. Peaks, Sacajewea Peak, diverse, mosaic, sharp elevational ranges. Rocky Mtn. and boreal species on Mtn. top islands, isolated. Unusual geology (limestone, greenstone, argillites), cold, snowy, many wetlands and springs.	Almost all wilderness; 2 RNAs within wilderness	No roads	Very low density	Very mixed: subalpine herb, spruce/fir, grand fir, lodgepole	All Wallowa Whitman National Forest, no BLM
RE5	Oregon: Deschutes, Three Sisters area, special habitats due to volcanos and other geological patterns.	Some wilderness to west, edge of Wild and Scenic River; TNC reserve; ACEC; RNA	Mod-low. Small area of high. None in wild.	Some areas of high density to east, low-very low to west	Interior ponderosa pine, Douglas fir, spruce/fir, Mtn. big sagebrush	2 National Forests, BLM, about 1/3 private/ other
RE6	Oregon: Upper Klamath Lake, many spring, alkali lakes, thermal areas, unique habitats for fish, invertebrates and plants. Human disturbance high in some areas.	Small: FWS refuge; ACEC; SIA; RNA	High, a little mod.	Mod., range from high to low	Interior ponderosa pine, agriculture, rangelands, sagebrush, marsh vegetation.	Mostly National Forest, some BLM and private/ other

Table 5.17 (continued).

Number[2]	Description/Location	Natural Area[3]	Road Density[4]	Human Density[5]	Vegetation	Ownership
RE7	Oregon: Summer Lake (westshore), marsh areas, fresh and alkali spring, important to fish, invertebrates, plants.	Slight: edge of WSA and SIA; RNA	High, very little low	Low	Interior ponderosa pine, rangelands, wheatgrass, sagebrush, marsh vegetation.	National Forest, a little BLM, small private/other
RE8	Oregon: Warner Lakes, Crump Lake, Hart Mtn. Refuge. Lakes, springs, alkali areas, important to fish, invertebrates and plants.	FWS refuge small ACEC, RNAs and WSA edge	Mod-low	Mod-low	Agriculture, salt desert shrub, sagebrush, wheatgrass, marsh vegetation.	Most FWS, BLM, no National Forest, small private/other
RE9	Oregon: Alvord Lake, Steens Mtns., alkali lakes, springs, lake, marshes, Great Basin species, insect research, high human disturbance.	Some WSA, 2 ACEC, RNA	Mod-low, small area of high	Low density	Salt desert shrub, wheatgrasses, antelope bitterbrush, sagebrush steppe, agric. and rangelands	Mostly 2 BLM, no National Forest, some private/other
RE10	Oregon: Ontario north to Huntington, Snake River, Weiser River. Sand pockets, gravels, lake beds, extremely low diversity in some areas, limestones, Great Basin arid grass/shrub communities, Snake River Canyon.	Small RNA	Mod	Very low to high, about 1/3 in mod-high	Mostly agricultural, rangelands, salt desert shrub, basin sagebrush, wheatgrass	2 BLM, private/ other, no National Forest
RE11	Idaho: Snake River from Oregon Idaho border to Grand View, part of Bird's of Prey Area. High contrast in river canyon to surrounding. River is corridor and unique habitat, geology, steep slopes, disjunct populations from south, limestone, sand, ash, unique soils. Grazing and mining conflicts.	Small ACEC, TNC	Mod-low	Very low to high, recreational use	Desert salt shrub, basin and Wyoming big sagebrush, agriculture and wheatgrass	A lot of BLM, no National Forest. Some private/ other
RE12	Idaho: Hot Springs south to Bruneau. Some Dept. of Defense. Hard bottom playa, clay soils. May have been isolated in past. Some highly adapted species, hot spring important to snail, inverts.	ACEC, WSA, WSR	Mod	Low-very low	Wheatgrass, rangelands, desert salt shrub, sagebrush, agriculture	A lot of BLM. No National Forest. Dept. of Defense, private

[1]Hot spots are defined as intersection areas of three or more centers of concentration of species' rarity or endemism among all taxonomic groups mapped.

[2]See map 5.4 for specific locations.

[3]Natural Areas: RNA = Research Natural Area, SIA = Special Interest Area, WSA = Wilderness Study Area, TNC = The Nature Conservancy reserve, FWS = Fish and Wildlife Service, WSR = Wild and Scenic River, ACEC = Areas of Critical Environmental Concern.

[4]Road Density: From predicted road density classes [ICBEMP GIS data (1 km^2 rater data)]: None = 0.00-0.01 km/sq km, very low = 0.01-0.06 km/sq km, low = 0.06-0.44 km/sq km, moderate = 0.44-1.06 km/sq km, high = 1.06-2.92 km/sq km, extremely high = 2.92+ km/sq km.

[5]Human density: Low = 0-3 people/sq km, moderate = 3-6 people/sq km, high = 6-30 people/sq km.

Table 5.18—Hot spots of species biodiversity[1] (see map 5.4 for locations of numbered areas).

Number[2]	Description/Location	Natural Area[3]	Road Density[4]	Human Density[5]	Vegetation	Ownership
B1	Washington: North Cascade, eastern edge, Pasayten Wilderness tied into Cathedral Park (BC), North Cascade and Manning (BC) National Parks. Glaciated landscape, rounded peaks, elevation and climatic contrast to surroundings, wetlands, bog, meadows, many rare plants. Large carnivores, amphibians, BC linkage.	1/3 Wilderness, WSA, TNC, 2 RNA (FS, Washington State)	None in north, low in south	Low	Subalpine fir/spruce, Douglas Fir, alpine and western larch, lodgepole, subalpine herb, Mtn. sagebrush, interior ponderosa pine	Mostly National Forest, and state forest, a little BLM and private.
B2	Washington: Saddle Mtn. to Yakima, part of Hanford (DOE) and Yakima Firing Range (DOD). Remnant sage/steppe, desert salt shrub, a lot of reptiles, breeding birds, amphibians. Active sand dunes, seeps, talus, riverine, slopes with deep soils, playa bottoms.	A little FWS refuge, a little WSR, Hanford and Yakama Firing Range have some reserve areas	Low in east, mod-high in south, none in middle. Some restricted	1/4 high (SW), rest low-mod.	Sagebrush/ bunchgrass, wheatgrass, agricultural, rangelands, desert salt shrub, bitterbrush	BLM, Dept. of Defense, Dept. of Energy, private/ other
B3	Washington/Oregon: Columbia Gorge from Cascade Locks to Mosier, Mt. Adams to north. Highly diverse, high elevation and climate contrast. Gorge/river is corridor and barrier. Unique plant communities, geology, soils. Volcanic activity, spring, falls, highly disturbed. West side outside ICBEMP boundary.	Small part of wilderness, FWS refuge, SIA. Gorge National Recreation Area; RNA	High	1/4 or more in mod-high, rest in low	Fir, hemlock, cedar, Douglas fir, oak woodlands, grand fir, ponderosa pine, rangelands, agricultural, sagebrush	2 National Forests; Columbia Gorge NRA; Yakama Reservation; private/other
B4	Oregon/Idaho: Wallowa - Whitman National Forest to Salmon River, Hell's Canyon, elevation and climate extremes, refuge and corridor. Basalt, limestone, granite, steep. Dry with springs/seeps/creeks as micro-sites. Very diverse. Heavy grazing in some areas.	WSR, wilderness, RNA	Mod-low	Low recreation pressure mod-high	Wyoming big sagebrush, wheatgrass, bunchgrasses, some subalpine herb	Mostly National Forest, some BLM and private/other.

Table 5.18 (continued).

Number[2]	Description/Location	Natural Area[3]	Road Density[4]	Human Density[5]	Vegetation	Ownership
B5	Idaho: Upper Snake River from Idaho Oregon border to Mt. Home A.F.B. Birds of Prey area. High elev. and micro-climate contrast. High diversity, as canyon acts as corridor between basin, mountains and valleys.	ACEC, TNC	Mod, none in canyon	1/4 mod high, rest low	Wyoming big sagebrush, Idaho fescue, desert salt shrub, agriculture, wheatgrass, rangelands	BLM, Dept. of Defense, private/other
B6	Idaho: Panhandle, St. Joe River, Clearwater. Some checkerboard ownership. High amphibian diversity, canyon refuge for many species from coast. Some warm, moist, low elevation. Ferns, red alder, cedar forests. Some heavy logging.	WSR, RNA	Mod	Low, some mod.	Interior ponderosa pine, cedar, Douglas fir, lodgepole	Almost all National Forest, some BLM, private/ other
B7	Montana: Flathead, Glacier Park, Blackfoot Reservation into Alberta to the north. Eastern portion out of ICBEMP boundary. Large carnivores, intact plant communities, subalpine and alpine Rocky Mtn, relatively undisturbed except in lower elevations.	Most in natural areas, 1/2 National Park; WSR; RNA; wilderness.	East: low to none, far west: mod-high	Low except in far west, and park visitor areas	Spruce/fir, interior Douglas fir, lodgepole, seral shrub, subalpine herb, alpine tundra, some agric. in west	Most National Park Service, some Blackfoot Reservation, National Forest, a little private.

[1]Intersection areas of 3 or more centers of concentration of biodiversity among all taxonomic groups mapped.

[2]See map 5.4 for specific locations.

[3]Natural Areas: RNA = Research Natural Area, SIA = Special Interest Area, WSA = Wilderness Study Area, TNC = The Nature Conservancy reserve, FWS = Fish and Wildlife Service, WSR = Wild and Scenic River, ACEC = Areas of Critical Environmental Concern.

[4]Road Density: From predicted road density classes [ICBEMP GIS data (1 km^2 rater data)]: None = 0.00-0.01 km/sq km, very low = 0.01-0.06 km/sq km, low = 0.06-0.44 km/sq km, moderate = 0.44-1.06 km/sq km, high = 1.06-2.92 km/sq km, extremely high = 2.92+ km/sq km.

[5]Human density: Low = 0-3 people/sq km, moderate = 3-6 people/sq km, high = 6-30 people/sq km.

Fewer centers of concentration and hot spots were delineated in the eastern portion of the Basin than in the western portion for several reasons. First, there were fewer available inventories and research studies of rare and endemic species in the eastern portion, especially northeast Washington and central Idaho, than in the western portion. Second, there appear to be more centers of concentration of species rarity and endemism in transition areas between the Pacific coast and the east side of the Cascades Mountains, and between the northern Great Basin and the southern Rocky Mountains, with fewer areas in the heart of the Rocky Mountians and central Idaho which have more uniform environments. Third, the panel members may have had greater experience in Washington and Oregon environments than further east in the assessment area. Although an effort was made to represent expertise from Idaho, Montana, Utah, and Wyoming, many panelists were from Oregon.

Of the 12 hot spots of rarity and endemism, nine occurred wholly or partly in Oregon, two on the Upper Snake River of the Owyhee Uplands and one in the Columbia steppe in Washington (map 5.4). Only three of these hot spots of rarity and edemism (Umatilla Plateau Mountains, Wallowa Mountains, and Snake River) had 25 percent or more of their area within designated existing natural areas. The remaining nine hot spots had about 10 percent or less within natural areas. This means that most of the hot spots of rarity and endemism are not necessarily being managed to protect the species and conditions identified by the panels.

The Umatilla Mountains, Wallowa Mountains, and Deschutes and Snake River areas appeared to be rarity and endemism hot spots because topographic, climatic, and geologic conditions have created unique and isolated habitats. The remaining areas also have some unique habitat features, especially thermal springs, alkali lakes, and marshes in southern Oregon, but they also contained rare remnants of native desert scrub and shrub steppe communities, which have declined rapidly in this century due to agriculture, livestock grazing, roads, noxious weeds, seeding, and human settlement. There also appear to be some critical habitat areas in southern Oregon that may have little protection for maintaining hot spots of rarity and endemism.

The Columbia River Gorge had the greatest convergence of centers of concentration of rarity and endemism, as well as many centers of high biodiversity. The unique topographic, geologic, and climatic extremes in this area and the dispersal corridor and barrier caused by the Columbia River and Gorge have created high species diversity and a high concentration of rare and endemic species. The area also may have received a higher degree of scientific inventory and study than other areas because of its proximity to Portland, and its scenic beauty, accessibility, and history. Tracts of private lands have been acquired by the Forest Service for addition to the National Recreation Area. Intensive visitor use could threaten this sensitive area. The rugged terrain provides some degree of natural protection to sites within the gorge, but the adjacent uplands have experienced greater human disturbance.

The Upper Snake River and Saddle Mountain areas of the Owhyee Uplands also appear as hot spots for rarity, endemism, and biodiversity. The Upper Snake River is similar to the Columbia Gorge, it has high topographic diversity, high contrast in climate and elevation, and unique geology. Like the Columbia River and Gorge, the Snake River and Gorge also serve as both a major dispersal corridor and a dispersal barrier for various species.

Map 5.4— Distribution of hot spots of species rarity and endemism and centers of biodiversity, with Ecological Reporting Units. These are locations that are particularly rich in species of plants, invertebrates, and vertebrates. See tables 5.17 and 5.18 for descriptions of each site.

Map 5.5— Distribution of centers of concentration of species rarity and endemism of plants and animals.

The Upper Snake area, where Great Basin species converge with Columbia Basin species, has high biodiversity, but it also has a high degree of species rarity and endemism because of the unique habitats and the effects of management activities in surrounding uplands. The Saddle Mountain Area is a refuge for some of the last intact areas of desert salt shrub and sagebrush steppe, which have been converted within the Basin to agriculture and livestock range. The Handford Energy Reserve and Yakima Firing Range have served to protect some areas of native sagebrush steppe from development, but this area contains virtually no BLM- or FS-administered lands.

Hot spots for biodiversity overlapped more with existing natural areas, especially wilderness areas, than did hot spots of species rarity and endemism. The natural areas tended to be in the upper elevation, forested portions of the hot spots, leaving at least some of the lower elevation portions of the hot spots unprotected from ground-disturbing human activities. For plants and large carnivores, there is likely a correlation between centers of biodiversity and natural areas or roadless areas.

Natural Areas Characterization

Natural areas fall into 26 categories of existing land allocations on FS- and BLM-administered lands, with varying management objectives, selection criteria, allowed uses, size ranges, and agency or organization administration. In the four western states most encompassed by the Basin (that is, eastern Oregon, eastern Washington, most of Idaho, and western Montana), Federal land management agencies administer a total of 41.63 million hectares. On these lands, 28 percent or 11.72 million hectares occur in natural areas (TS 1995).

Natural areas throughout the Basin were designated under a single management objective or strategy, in contrast to more consistent approaches to natural area management in British Columbia, Canada, and in New Zealand, India, or other countries (Joshi and Gadgil 1991, Pressley 1994).

Some Ecological Reporting Units (for example, Central Idaho Mountains and Northern Glaciated Mountains) have large natural areas, whereas others (for example, Columbia Plateau, Upper Snake) have only very small and isolated natural areas, and throughout the Basin the locations of natural areas do not consistently correspond to centers of concentration or hot spots of biodiversity or species rarity or endemism.

Based on home range sizes of vertebrates, even the smallest natural areas (less than or equal to 50 ha) could support at least one individual, and perhaps small populations, of 70 percent of vertebrate species (fig. 5.8). Based on area alone, natural areas larger than 650 hectares could support 90 percent of the vertebrate species from the region; approximately 50 percent of the natural areas are larger than 650 hectares. Natural areas would have to be at least 10,000 hectares in area before 99 percent of the vertebrate species could be supported. Only 16 percent of the natural areas are larger than 10,000 hectares.

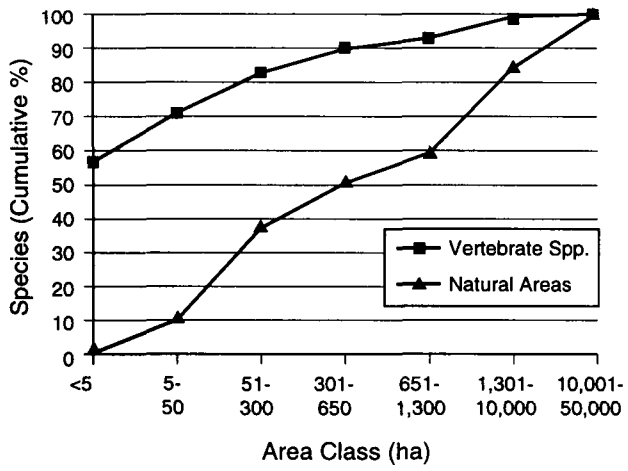

Figure 5.8—Cumulative percentages of vertebrate species by home range area, as compared with cumulative percentages of natural areas by size.

Expectations of species occurrence based on home range size does not necessarily mean that a particular size natural area would contain viable populations of all associated species. Natural areas would have to be several times larger than the area of an individual home range of most species to support enough individuals for a viable population. The area multiplier necessary for sustaining viable populations would depend on the population structure, life history, habitat relation, and behavior of the species. Habitat composition, pattern, disturbance regimes, and connectivity throughout surrounding landscapes also are critical considerations.

Of the 389,009 kilometers of streams in the Basin, 51,293 kilometers (13%) occur within existing natural areas. Most streams are within wilderness or wilderness study areas with the headwater, high gradient and steep portions of streams over-represented as compared to the low gradient, lower elevation portions. Only 7 of the 132 4th-field Hydrologic Units [HUC] inventoried did not have at least 1.6 kilometers of stream within a natural area. An average of 386 kilometers of stream occurred per 4th-field HUC. Some categories of natural areas, namely the research natural areas, areas of environmental concern, special interest areas, and wild and scenic river areas, have been established specifically to protect only a portion of a stream, lake or river. These areas are generally small and linear and do not include protection of uplands that may be critical to maintaining the health of the aquatic system. There are 2,150 lakes covering 97,242 hectares within natural areas.

Biogeography

Much of the above discussion of species groups has touched upon various aspects of biogeography of species. In particular, reasons for distribution and abundance and response of population to broad-scale biophysical attributes has been discussed. We identified species with disjunct, peripheral, scattered, regionally endemic, and locally endemic distributions. We also identified some species closely associated with some of the nine landform classes. Some species are closely associated with single biophysical factors, although many species are likely correlated with multiple factors. Most ERUs had at least some unique species, although many species overlapped several units. A few additional examples here help illustrate some general principles of species biogeography within the Basin.

Landforms

Nine general landform categories have been identified in the Basin. In some cases, significant biogeographic correlates with some species distributions are readily apparent by simply matching species distribution with these landforms. An example of a species that tightly associates with highland landforms (glaciated and unglaciated mountains and breaks) is the carpenter ant (map 5.6). Likewise, pronghorn shows alignment of its distribution with lowland landforms (map 5.7) as well as with areas of low precipitation (map 5.8); and lowland landforms and low precipitation are correlated. The distribution of pronghorn also demonstrates another simple biogeographical principle, that species can be shown to be distributed according to several biophysical factors, themselves correlated.

Disjunct Distributions

Another example of biogeography of species in the Basin pertains to disjunct distributions. In some cases, species such as mountain goat (maps 5.9a, b, c) that are associated with highland landforms appear as several disjunct populations because of the disjunct distribution of such landforms within the Basin. The mountain goat has been mapped as having 12 disjunct population centers in the Basin. The mountain goat seems closely tied to high elevation and high topographic relief, specifically with the highest elevation marked in each 6th-field HUC as mapped in the Basin.

The map of mountain goat distribution and highlands (map 5.9a) also illustrates a lesson in how map resolution affects interpretation of species biogeography. At the broadscale used in this assessment (1 km^2 map cells), east-central Idaho is shown as very high elevation and thus as potentially suitable habitat for, and within the range of, mountain goat. At a finer resolution, however, this area contains three valleys separated by narrow mountain ranges (Big Lost River-Challis Creek valleys, Little Lost River-Pahsemeroi River valleys, and Birch Creek-Lemhi River valleys). It is unlikely that any mountain goats that may occur in the inner ranges would travel between these three ranges.[36] Thus, at a finer resolution, there may appear smaller and more localized, disjunct goat populations than were indicated by the broad-scale information.

Species with disjunct ranges pose interesting biogeographic questions. Some, such as the longnose snake (see map 5.2b), are poorly known. The longnose snake's disjunct pattern in the southern periphery of the Basin and along the Snake River is as yet unexplained. It selects for open or closed, low and medium shrub environments, sometimes near agricultural land and urban areas, and probably occurs in a wider range of habitat types than current literature suggests. It may be that its apparent disjunct distribution is an artifact of inadequate sampling. The same may be true, to some extent, with the California mountain kingsnake and western ground snake (map 5.2b). On the other hand, the disjunct pattern of wild turkey (map 5.2b) most likely is due to selective introductions in the Basin.

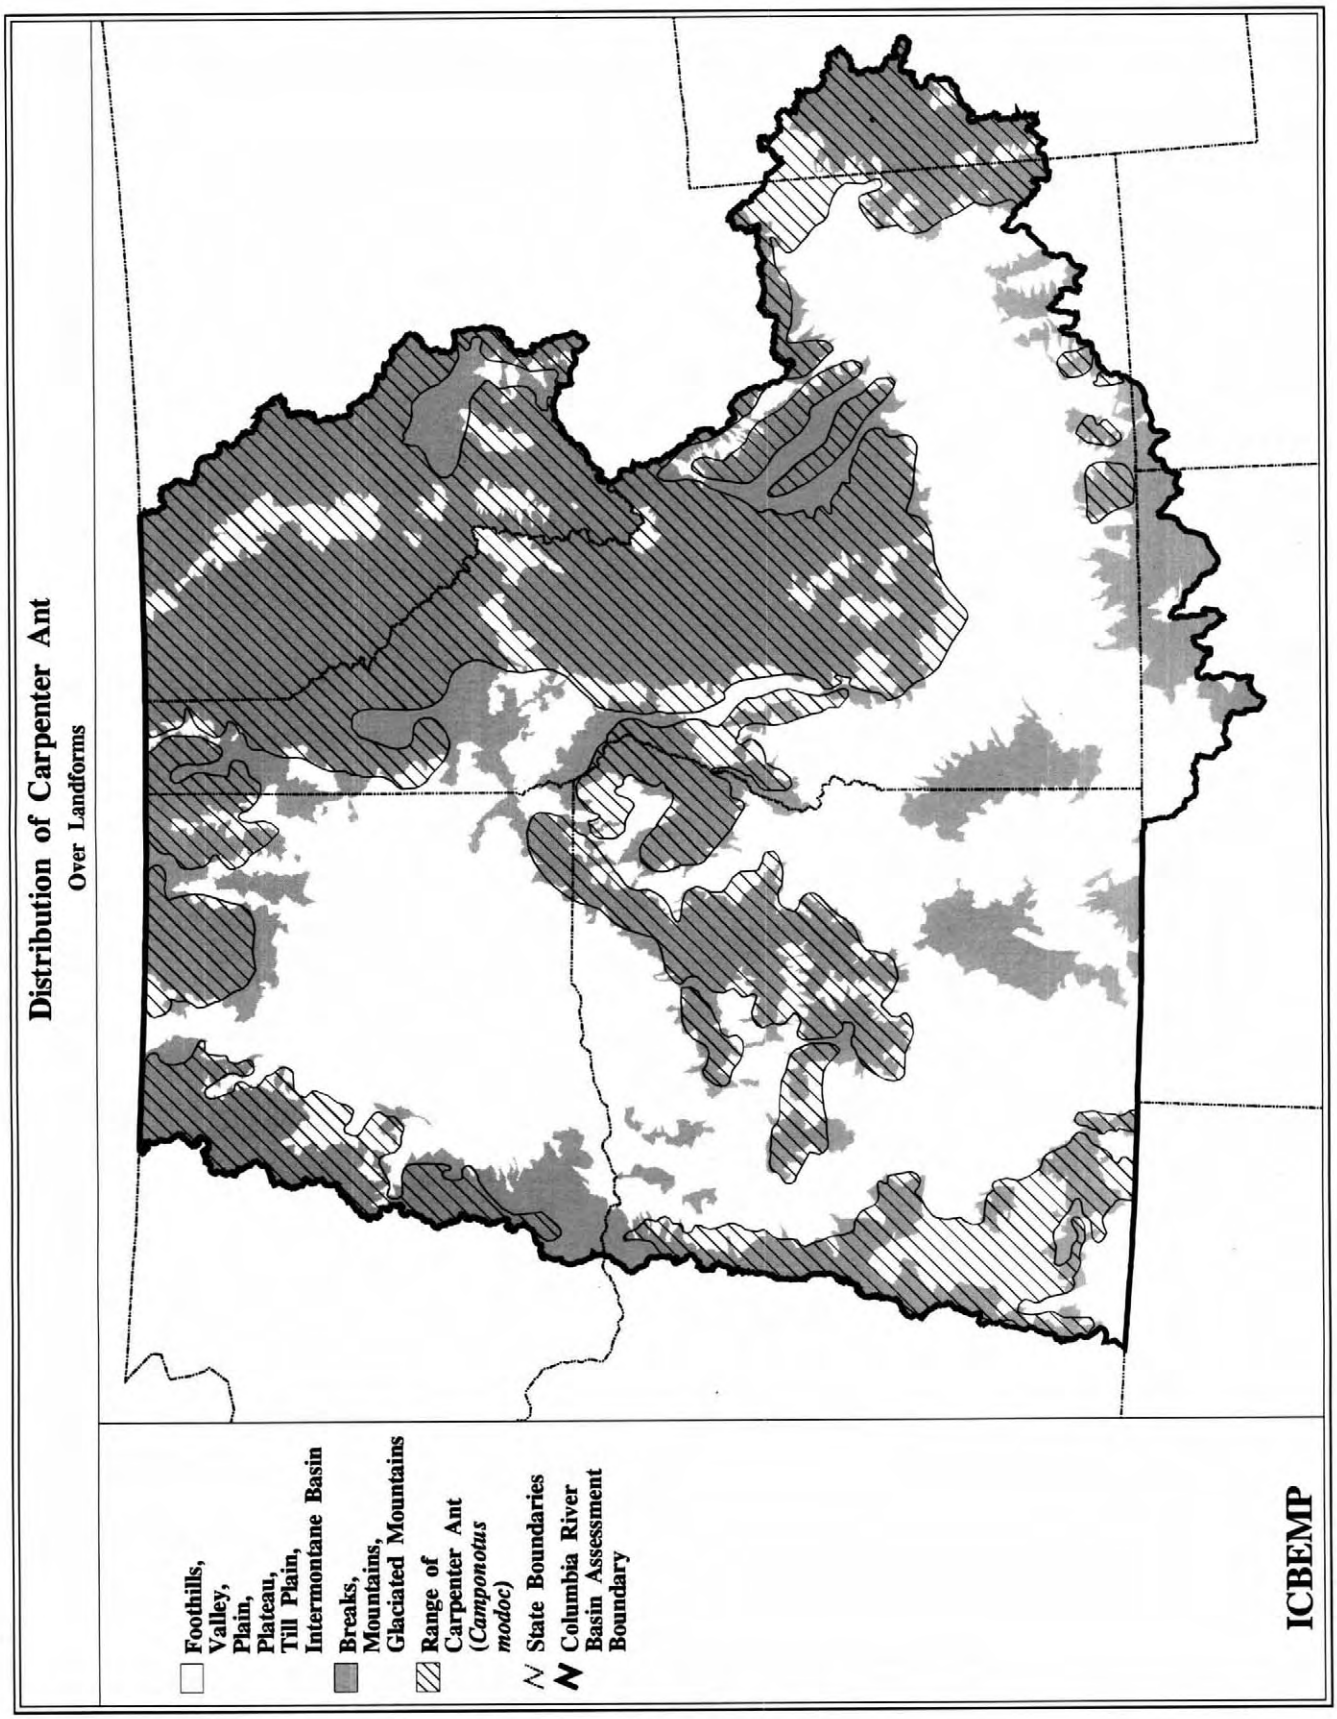
Local Endemics

Distributions of collective "hot spots" of locally endemic species were discussed above. Specific examples of locally endemic vertebrates are shown in map 5.10a and 5.10b (appendix 5H). In these examples, many of the species are restricted to specific ranges because of their high habitat specificity. One example is Coeur d'Alene salamander, which selects sites with talus, seeps, and spray zones of waterfalls, with a slope of 10 to 60 percent, above elevations of 400 meters. Suitable sites usually have at least 25 percent canopy cover. At the broadscale, they are found in fractured belt rock formations in the northern Rocky Mountain extension in northern Idaho and northwestern Montana. At the mid-scale within these sites, they select for appropriate elevations, slopes, vegetation cover, and stream or waterfall proximity.

Ultimately, distributions of local endemics can be a result of contracted ranges due to habitat loss or extirpations, overall scarcity of suitable environments, or other factors. The extent to which glaciation and paleoclimates played a role in determining current distributions of locally endemic populations, particularly of invertebrates and plants, in the Basin is not well studied.

Endemics tend to be less studied than other species, at least among vertebrates. The median confidence levels in scientific knowledge as ranked by the expert panelists were significantly lower for the 39 locally or regionally endemic vertebrate species than for all other vertebrates ($P<0.001$, log-likelihood ratio test, $G=859.27$, $DF=3$).

Other Patterns of Endemism and Distribution



Plants and allies and vertebrates were specifically coded in the SER database according to the five classes of species distribution (that is, scattered, regionally endemic, locally endemic, peripheral, and disjunct). Species of plants and allies included in this study are those listed as threatened, endangered, or candidate, or those suggested by the plant expert panels for such listings.

[36]Personal communication, 1995. Allen E. Thomas, Fish and Wildlife Biologist. U.S. Department of Interior, Bureau of Land Management, Idaho State Offic, 3380 Americana Terrace, Boise, Idaho 83706.

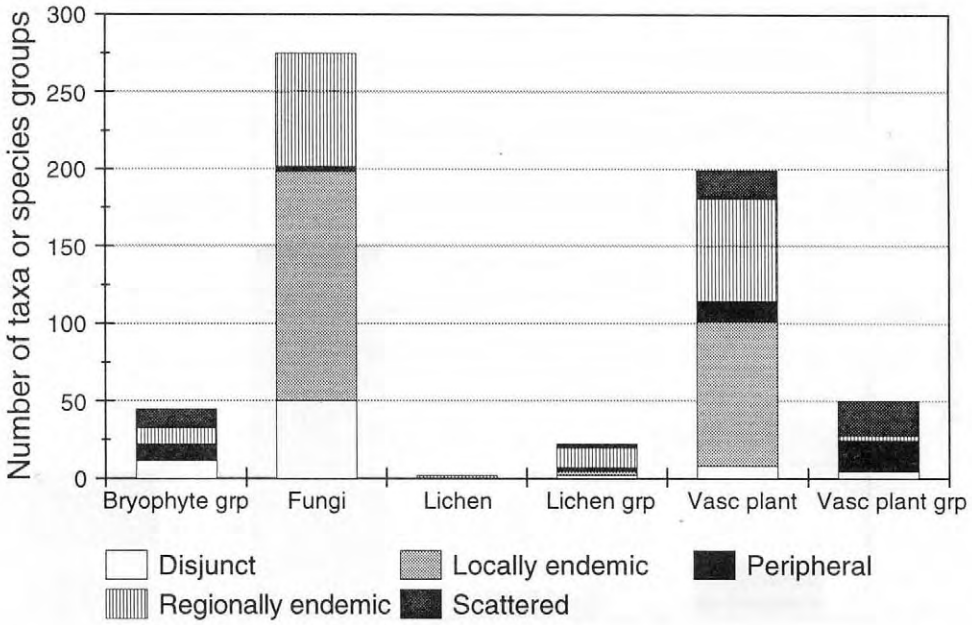

Figure 5.9— Numbers of endemic taxa of plants and allies by endemism category, and taxonomic or species group.

Thus, they already include many of the rarer taxa. In the Basin, bryophyte groups were equally numbered among categories of scattered, regionally endemic, peripheral, and disjunct distributions; none were identified as locally endemic (fig. 5.9). Nearly 70 percent of the lichen groups were identified as regional endemics. Most of the vascular plant groups were either scattered or peripheral, with a few regional endemics and disjunct distributions.

Among individual species, most of the 394 fungi for which distribution patterns were identified were local endemics (about 55%). Others were largely regional endemics or had disjunct distributions. Distributions of vascular plant species listed in the database included scattered (over 40%) or peripheral (approximately 40%) patterns, with the rest (approximately 20%) regionally endemic or disjunct. However, patterns of the entire flora of the Basin, including more common species and species not listed or of specific conservation concern would likely differ.

Among all vertebrates in the Basin (figure 5.10), amphibians and mammals each included all five endemism classes. Reptiles included (in decreasing frequency) species with peripheral, scattered, and disjunct distributions, with none locally endemic. Many birds were peripheral or scattered in distribution, with only a few regional endemics; none was locally endemic. The lack of local endemics at least among reptiles and birds may be explained by the geologic youth of much of the Basin (particularly in the largely volcanic Owhyee Uplands and Columbia Plateau ERUs, and the Northern Glaciated Mountains ERU).

The numeric pattern of local and regional endemics among amphibians, reptiles, birds, and mammals was not significantly different than the pattern among all non-endemic vertebrates; local and regional endemics were not more apt to be of one particular vertebrate class ($P>0.99$, log-likelihood ratio test,$G=-469.06$, $DF=2$). However,

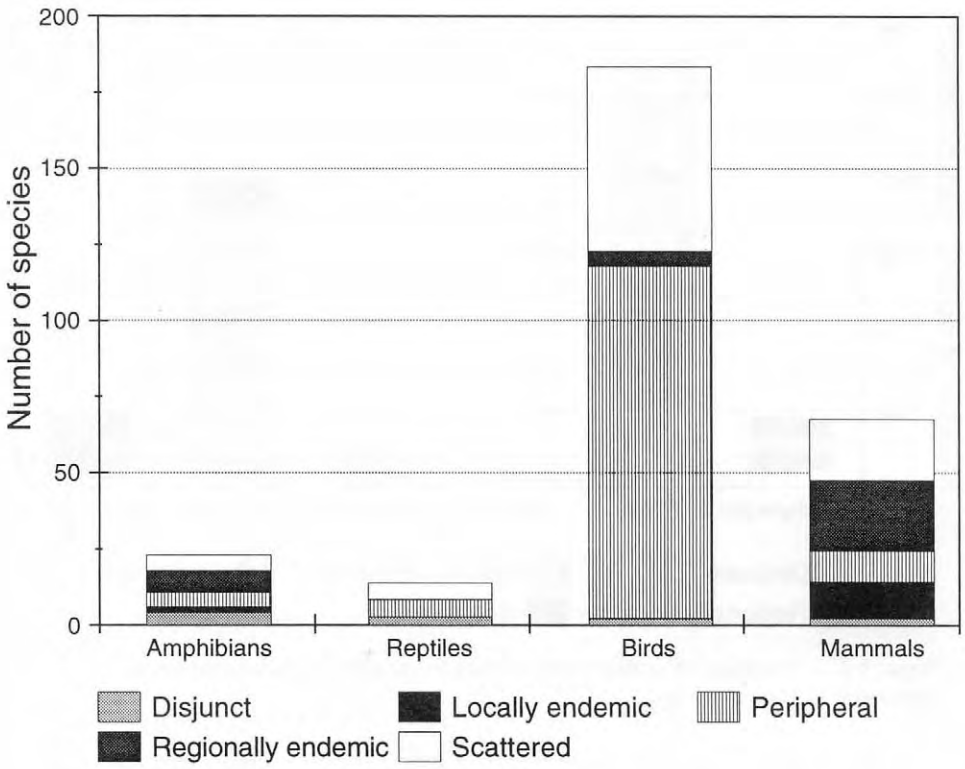

Figure 5.10— Numbers of endemic taxa of vertebrates by endemism category and taxonomic class.

locally and regionally endemic vertebrates did tend to be federally listed more often (as C2 candidate species) than did non-endemic vertebrates ($P<0.01$, log-likelihood ratio test, $G=10.43$, $DF=2$). This is explainable in that endemics, in general, tend to be more subject to greater viability risk.

Some boreal and mid- to high-elevation vertebrate species, including common loon, pine grosbeak, water vole, and hoary marmot, appear to occur as disjunct populations in the northern portion of the Basin along the Canadian border. Actually, these species join in distribution further north in British Columbia. Other northern species, including the great gray owl, spruce grouse, chestnut-backed chickadee, northern flying squirrel, and northern bog lemming, nearly show this disjunct pattern but join in a narrow band in the United States along the northern Washington-Canada border, making this portion of the Basin key in linking such northern vertebrate populations within the United States. In addition, the inclusion of the portion of the northern Great Basin in southeastern Oregon accounts for many of the peripheral species on these lists (see discussion below).

Thus, apparently peripheral, disjunct, and scattered distributions of some species may be an artifact of the location and size of the area of interest, even with an area as large as the Basin of the present study. This principle operates at several scales. For example, at the global scale, distributions of Palearctic species such as boreal owl and Neotropic migratory species such as flammulated owl would seem peripheral or disjunct in North

America alone unless their entire global range were considered. Thus, to better understand the contributions of local conditions, local species distributions should be interpreted in context of one or two larger geographic areas.

A number of the ERUs host unique vertebrate assemblages for a variety of reasons (table 5.19). In some cases, species are specific to particular ERUs because their ranges correlate with landform, vegetation, climate, or other biophysical parameters of the inland Northwest. In other cases, species appear somewhat peripheral to the Basin because they associate with other major ecosystems of the continent, such as the Great Basin, Klamath Lakes, central Rocky Mountains, or even the prairie region.

Certainly, not all species can be shown to have such obvious correlates with broad-scale biophysical features. One result of our investigation suggests that the specific environmental requirements of a number of species simply cannot be adequately analyzed or depicted at the scale of this assessment. Such species include most invertebrates and many rare plants, which often associate with conditions that can be described only at highly site-specific levels. Reviewing their general distribution at the broadscale is only a prelude to conducting further, more in-depth viability analyses. Additional factors come into play at more local geographic areas and finer resolutions (De Cola 1994).

Table 5.19—Unique vertebrate assemblages found in various Ecological Reporting Units (ERUs) within the Basin. Listed are at least some of the species (grouped by taxonomic class) within the assessment area that are found mostly or solely within the identified ERUs.

Upper Klamath Basin ERU

Most of these species are found only in the extreme southwest corner of the assessment area, in the Upper Klamath Basin ERU outside the Columbia River Basin *per se*. Most of these species' ranges extend south to California or west over the crest of the Cascade Range. These are largely species associated with coastal influence.

western pond turtle (also in Columbia Gorge)
foothill yellow-legged frog
acorn woodpecker
wrentit
California towhee
tricolored blackbird
red-shouldered hawk
green heron
Brazilian free-tailed bat
Botta's pocket gopher
broad-footed mole
California kangaroo rat
dusky-footed woodrat

Owyhee Uplands ERU

Most of the ranges of these species enter the assessment area from the south. Some of these species ranges also overlap slightly into the adjacent Northern Great Basin ERU to the west (also see list below). Most of these species belong to arid grassland or steppe habitats but do not extend further north into the Columbia Plateau ERU or Snake River Plain ERU.

western whiptail
mojave black-collared lizard
desert horned lizard
longnose snake
ground snake
kit fox
Wyoming ground squirrel
desert woodrat
little pocket mouse

Table 5.19 (continued).

Northern Great Basin ERU

These are species of the northern Great Basin, only a small portion of which occurs within the assessment area, and which is outside the Columbia River Basin *per se*. These species are part of a much more extensive and characteristic Great Basin fauna more fully represented further south beyond the assessment area. Most of these species' ranges extend further east and south out of the assessment area. Some of them also overlap slightly into the Owyhee Uplands ERU to the east within the assessment area.

rose-breasted grosbeak
(also disjunct in Snake Headwaters ERU, below)
western snowy plover
chisel-toothed kangaroo rat
dark kangaroo mouse

Amphibians in the Columbia Gorge

This is a special set of species—all amphibians—which just enter the assessment area east of the crest of the Cascade range, through the Columbia River Gorge (mostly along the northern reaches of the South Cascades ERU, which includes much of the western section of that portion of the Gorge that occurs in the assessment area). The Columbia Gorge provides unique mesic conditions and habitats allowing this assemblage to extend just east into the assessment area.

Dunn's salamander
Larch Mountain salamander
Cascade torrent salamander
red-legged frog
Oregon slender salamander

Spine of the Cascades

This set of species occurs mostly along the spine and west of the Cascades in Washington and Oregon (mostly the North and South Cascades ERUs, but in some cases further south into the western edges of the Upper Klamath Basin ERU). There, they edge into the westernmost periphery of the assessment area along the Cascades high country and eastern slopes.

Cascades frog
rough-skinned newt
northwestern salamander
Cope's giant salamander
ensatina
northern spotted owl
hermit warbler
Trowbridge's shrew
shrew-mole
Cascade golden-mantled ground squirrel
Pacific jumping mouse
mountain beaver
western red-backed vole
creeping vole
black-tailed deer

Snake River Headwaters ERU

This assemblage consists mostly of mid-continental and eastern United States species that just edge into the assessment area in western Wyoming.

yellow-bellied sapsucker
brown thrasher
bay-breasted warbler
chestnut-sided warbler
summer tanager
rose-breasted grosbeak
(also disjunct in Great Basin ERU, above)
dickcissel
Sprague's pipit
black-throated blue warbler
red-throated loon
whooping crane
black scoter
parasitic jaeger
Uinta chipmunk
American bison

Table 5.19 (continued).

Upper Snake River ERU

A few species enter the assessment area from the south into the Upper Snake River ERU in southeastern Idaho.

Virginia's warbler
cliff chipmunk

Northern Glaciated Mountains ERU

A few species barely range into the assessment area from the north in a portion of the Northern Glaciated Mountains ERU. Some, like northern hawk owl, snowy owl, gyrfalcon, boreal chickadee, lynx, and others, occur in the north fringes of the assessment area, largely in the Northern Glaciated Mountains ERU and adjacent northern ERUs. Some of these species occur only in winter during irruptive, southward range expansions. At least the three following species, however, appear to occur permanently mostly in very northern Idaho and northeastern Washington.

wood frog
green frog
caribou

Columbia Plateau ERU

There appear to be few vertebrate species found solely in the Columbia Plateau ERU.

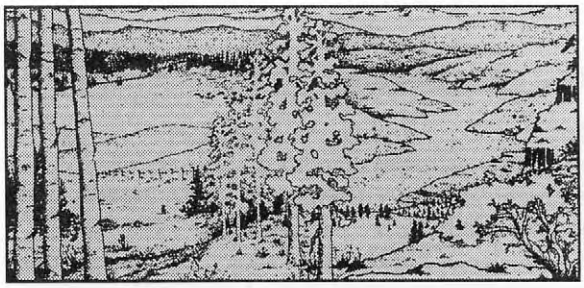
Washington ground squirrel

Central Idaho

These species occur solely or mainly in the Lower Clark Fork ERU or Central Idaho Mountains ERU.

Idaho giant salamander
Gambel's quail
Idaho ground squirrel

Western Montana



A few species distributed more easterly or northerly enter the assessment area in western Montana, in the Lower and Upper Clark Fork ERUs or the Northern Glaciated Mountains ERU.

Tennessee warbler
clay-colored sparrow

CONCLUSIONS AND INTERPRETATIONS

This chapter has provided an overview of the status of terrestrial species and ecological communities in the Basin. This chapter has focused, in part, on species of current viability concern, particularly species currently designated as endangered, threatened, or candidate, and species of potential concern for persistence because of management activities. This species-centric focus is but one facet of the broader evaluation, however. Equally vital to meeting the demands of a new era of ecosystem management is an understanding of species (and other taxa) relations and their ecological functions, and how these affect long-term ecosystem productivity, biodiversity, and sustainability of resource use. To this end, we have collected a vast amount of information on species and communities in the form of contract reports, databases, maps, and internal reports.

Our work provides an ecosystem context for management of habitats and environments for terrestrial species and communities. We provide a classification system for environmental correlates and for ecological functions of species, and identify functional groups of species based on their ecological roles. Although the Forest Service and Bureau of Land Management are primarily charged with habitat management, knowledge of such ecological roles of species and the dynamics of plant and animal communities provides a stronger knowledge base and ecological foundation for ecosystem management.

In this chapter we have not considered future scenarios or planning alternatives, and thus do not project future viability of species. However, this assessment sets the stage and provides base information, such as distribution of species, habitats and key environmental correlates of species, and effects of management actions, as a basis for viability evaluation.

Our work also addresses ecosystem restoration in several ways. We suggest selection of bioindicators for monitoring environmental changes and for assessing problems of grassland deterioration and specific actions for mitigation and restoration.

Some policy questions and issues can be addressed at a broad regional scale. Additional work is necessary for (1) further describing historical trends and current conditions and threats for species at finer scales of resolution that this current study affords, and (2) collecting basic scientific knowledge on life history, ecology, and distribution of many species.

Our work provides a basis for considering species in ecological and spatial contexts, and listing species according to biological criteria. One example likely deserving greater exploration for its utility in management is The Nature Conservancy's global ranking system. This system ignores administrative boundaries, lists species based on ecological criteria by ecosystem, is widely accepted, and contributes meaningfully to conserving biodiversity.[37]

Major Findings

Biological Diversity

Based on our research, the total biodiversity for the Basin is greater than 43,000 species of macroorganisms. The enormity of the biota is matched only by the paucity of our scientific knowledge of life history, ecology, and response to management activities of most species. Among terrestrial species, the better-known forms include some of the commercially valuable plants, a few of the rarer plants, the more conspicuous or economically important vertebrates, and defoliator insect species. The rest of the terrestrial biota is largely unstudied in the Basin. The enormously diverse microbiota—the microfungi, bacteria, protozoa, rotifers, nematodes, and others, vital to soil productivity and ecosystem function—is virtually unknown.

We identified numerous centers of concentration of plant and animal species rarity and endemism, and of high biodiversity, throughout the Basin. Where these centers overlap, they formed 12 hot spots of species rarity and endemism and 7 hot spots of high biodiversity. Our identification of "hot spots" of species rarity, endemism, or biodiversity can be the starting point for considering management for such conditions [for example, see Kruckeberg and Rabinowitz (1985) on conservation of rare and endemic plant species]. For example, hot spots are areas of intersection, not union, among pertinent species; they do not capture all potential sites with rare or endemic species or areas with high biodiversity.

Other aspects of a broader biodiversity conservation strategy can address protecting type locations of rare fungi, lichens, bryophytes, and vascular plants; protecting unique plant communities; *ex situ* plant conservation measures; providing for plant and animal species associated with rare or declining vegetation communities, especially native grasslands, native shrublands, and old-growth forests; ensuring adequate habitat for plant and animal species of interest to American Indian tribes; and conserving locations still containing all top vertebrate carnivores. Also, natural areas of various kinds might be "realigned" or enhanced to better coincide with hot spots of species rarity and endemism and hot spots of high biodiversity. Criteria for selection of new natural areas could be based on consistent ecological themes.

We have also provided some information on maintaining biodiversity by addressing the role of natural areas, changes of habitats and species on Federal and non-Federal lands, identifying sets of substrates and environmental correlates associated with individual species, and other information.

The models of Joshi and Gadgil (1991) also suggest that refuges for renewable resources, such as for harvestable plants or animal populations, can significantly contribute to long-term sustained use throughout a region. Such centers of renewal also can contribute to ecosystem management objectives for maintaining biodiversity, and might be considered in management planning.

Species at Risk

We have developed a complete catalogue of all federally listed threatened, endangered, and candidate species. The database also includes information on

The Nature Conservancy and Heritage Program rare plant categories, and state- and agency-specific listing categories of all species. We have provided summaries of conservation plans and useful management actions for federally listed species. It is evident, though, that some of the threatened and endangered species, and many of the additional species of potential conservation concern, are dependent on environmental or habitat components not evaluated at the broadscale.

We also identify a number of additional taxa, especially plants and invertebrates, worthy of additional attention. These potentially include: 394 fungi species; 40 functional groups of lichen species; sundry types of microbiotic crusts (not classified); at least 400 apparently regionally rare bryophyte species; 280 individual vascular plant species and 82 rare plant communities; 144 rare

and endemic invertebrates (gastropods and insects); and various vertebrates, including the more aquatic-dwelling amphibians, reptiles susceptible to ground-disturbing management activities, and birds and mammals associated with habitats that are now scarce, declining, or increasingly fragmented, including native grasslands, sagebrush, and old low- and mid-elevation forests. Basic inventories are needed for many of these species to determine their true rarity.

However, we do not advocate a species-by-species approach to management of all such species at risk. Many of the species of these lists can be assessed in groups; inventories, where desired, could aim at gathering information for many species simultaneously; and management guidelines could address their collective habitat and environmental requirements, or locations of joint occurrence.

Species and Habitat Trends

Conclusions made regarding habitat trends, particularly regarding potential effects on species, must be treated as tentative working hypotheses. The lack of specific data on population size, structure, and functional and numerical response means that much inference has to be made from changes in habitat abundance and gross distributional patterns. Actual population response to changing habitats and environmental conditions might differ. Likewise, many finer-grained attributes of vegetation and habitat substrates and spatial patterns of suitable environments cannot be accounted for because of the necessarily broad geographic extent and coarse resolution of this project. These, too, might act to affect true population response. Thus, one working hypothesis arising from this project is that habitat amount, distribution, and trend as analyzed in this study reflects true population size, distribution, and trend at both broad and finer scales of spatial resolution. Obviously, this hypothesis must be tempered by local knowledge of environments and populations when using the results of this study to guide land management.

Given these cautions, our research (also see Biophysical and Landscape Dynamics chapters) supports the hypothesis that species incurring the greatest likely changes from habitat conditions prevalent during the early nineteenth century seem to have been those associated with native closed shrublands (for example, big sagebrush), native grasslands (for example, *Fescue*-Bunchgrass and *Agropyron* bunchgrass), late-successional forests, and old open ponderosa pine forests. Most of the decrease in these areas has occured on non-Federal lands, although Federal (FS, BLM) lands also share some decrease.

Among vertebrates closely associated with old forest stages, which have greatly declined since historic times, are: three federally listed species or subspecies that occur on the periphery of the Basin (marbled murrelet, northern spotted owl, woodland caribou); and three woodpeckers (Lewis' woodpecker, pileated woodpecker, and Williamsons' sapsucker).

Six vertebrate species are highly associated with old forest structural stages (that is, occur in old forest structural stages and also use less than 20% of all 10 other possible structural stages): flammulated owl (*Otus flammeolus*), boreal owl (*Aegolius funereus*), brown creeper (*Certhia americana*), band-tailed pigeon (*Columba fasciata*), white-winged crossbill (*Loxia leucoptera*), and western grey squirrel (*Sciurus griseus*). An additional 17 old-forest species also use less than 30 percent of all 10 other possible structural stages, an additional 13 old-forest species also use less than 40 percent of other stages, and an additional 19 old-forest species also use less than 50 percent of other stages; these are all species allied to old forests but in decreasing degrees of requirement (TS 1995).

Overall loss of habitat is but one of several means by which species can decline. At least four types of declines can be identified (for example, see Gilpin and Hanski 1991). (The same categories can be used to explain increases, as well.) Altering total area of suitable habitat is only one measure. The four categories of species decline can be used as part of a process for better identifying species sensitive to particular land management activities.

First, species can decline by loss of portions of their distributional range but species' density in remaining habitats is more or less unchanged. This is the major kind of change analyzed in this project. It is the kind most amenable to broad-scale analysis.

Second, species can decline by loss of range-wide density, retaining their overall distributional range. For some species this is a matter of scale; loss of one stand of old trees might eliminate a red tree vole colony and cause overall densities of the voles to decline over a broader landscape area, even though their overall distributional range is unchanged. Some of the wider-ranging predators, including northern goshawk, wolverine, American black bear, and mountain lion, have likely suffered this kind of decline. We have not been able to quantify this kind of decline for species at the broadscale.

Third is a change in the degree of connections among habitats. Imposition of unsuitable conditions might act as behavioral or physiological barriers to species movement or colonization. In this case, overall range and ecological densities might remain mostly the same, but there is a low likelihood of occupying more fragmented or isolated habitats. This might have occurred with some of the aquatic species including some amphibians and aquatic mammals, whereby water diversions or dams could impose dispersal barriers to reaching habitats. Other examples could be disruption of transitional range of some ungulates that altered their migration between, and use of, summer and winter ranges. At the broadscale, our analyses of connectivity of vegetation cover types and of size classes of natural areas as compared to species' home range sizes attest to this kind of decline. Our findings on effects of mid-scale fragmentation of habitat patches will help identify vertebrate species and groups affected by this third kind of decline.

The fourth type of decline is a combination of range loss, density declines, and habitat made inaccessible. Probably all the species affected by the first three types of decline also suffer, to some degree, from changes in all categories. Also as revealed in our evaluations, various management activities can change species ranges, densities, and habitat accessibility.

Implications for Ecosystem Management

Using an ecosystem approach to land management implies maintaining the biodiversity, productivity, and sustainablility of renewable resources. Our work has highlighted aspects of biodiversity that may be considered under such an approach: identifying taxonomic diversity of species; diversity of species groups; diversity by ecological functions; areas of high species richness and species rarity or endemism; unique species assemblages by ERUs; and trends, current status, and needs for listed and candidate species.

Our results suggest that long-term conservation of inland ecosystems would entail focusing not only on specific taxa at risk but also the key ecological functions afforded by both rare and widespread elements of the biota. To help organize thinking on which substrates and ecological functions pertain to maintaining biodiversity and ecosystem processes, we developed the first classifications of key environmental correlates (appendix 5F) and key ecological functions (appendix 5G) that span all taxonomic groups of macroorganisms in the Basin. These classifications can be used to organize assessments of management activities and as a basis for developing more site-specific databases to help ensure that all major groupings of substrates or correlates and ecological functions are considered in management planning.

Classifications of environmental correlates and ecological functions can be used with the Species-Environment Relations (SER) database, itself just a first step in developing a fuller knowledge base of all taxa, to determine species associated with: vegetation cover types, structural stages, and specific substrates, as well as other environmental correlates, ecological functions, and, for some species groups, potentially threatening management activities. In this way, potential conflicts

between a species-oriented planning strategy and a "systems"-oriented one resolve into one coherent approach.

Grouping species by key environmental correlates or by key ecological functions is an ecologically-based approach. However, this should not preclude addressing management needs by also grouping species according to more political or management criteria. One classic such grouping is that of game species (or more focally, big game) and more recently, nongame species. Other examples might include species addressed by interest groups, such as particular sets of "old-growth species." The SER database approach can facilitate exploring ecological characteristics of such species groups as well. On a more ecological basis, species associated with snags, cavity use (primary or secondary), down wood, native grasslands, native shrublands, and old-growth forests also can easily be identified in the SER database and the Heritage Program databases of rare plant locations (integrated into the ArcInfo® data files). Managers often need to be able to assess species groups defined based on such political or management criteria and to monitor sustainability of their particular habitats. It must be remembered, however, that some entire taxonomic classes, such as most invertebrates and plants, likely respond to environmental conditions at scales far finer in resolution than currently afforded in the broad-based scope of the SER database.

One of the specific objectives for ecosystem management could deal with maintaining the long-term evolutionary potential of species lineages (properly, ecosystems, communities, and species groups do not evolve *per se*). Provision of the following key components would help meet this objective:

- all populations of species with disjunct distributions;
- locally and regionally endemic species;
- locally endemic subspecies, particularly those at the edges of their range;
- unique assemblages of species and their ecological functions and interactions, even if on the periphery of the Basin;
- all categories of species' ecological functions rather than allowing one species with a similar function or habitat orientation to "substitute" for another (no ecologically functional equivalents);
- the full array of vegetation cover types, structural stages, and substrates, particularly those in greatest decline since early historic times in the Basin; and
- both *in situ* and *ex situ* plant conservation measures.

In addition, further work is needed to describe the genetic constituents of many populations, for at the heart of long-term evolutionary potential is a species' ability to adapt to changing environments by tapping into a genetically diverse gene pool.

Given the ever-changing nature of ecological communities in the Basin, particularly regarding potential effects of fire, perhaps the very concept of defining "desired future conditions" for planning could be replaced with a concept of describing "desired future dynamics." That is, long-term evolutionary potentials can be met only by accounting for potential future changes in conditions. No one condition can be static for long; witness the recent eruptive, intense fires in parts of the Basin, resulting, in part, from a long history of fire suppression and vegetation changes. Impending changes in regional climates, too, have the capacity of causing great shifts in composition of ecological communities. For example, providing for elevational "corridors" to allow upslope shifts of vegetation over the next several decades may be vital to helping conserve the long-term evolutionary potential of individual species.

Maintaining evolutionary potential also entails conservation at various taxonomic levels. To this end, further work is needed in detailing community structure, historic and future changes, and levels of habitat specificity and endemism of

genera, families, and orders. Studying special conditions of allospecies complexes, sibling or cryptic species, species at the periphery of their overall range, locally endemic subspecies, and hybridization, provide unique opportunities for exploring mechanisms and instances of the speciation process (natural evolution of new species lines). Evolutionary potential is not indexed solely by a catalogue of species and their habitats. Additional study is needed on how manipulation of natural processes, such as fire and ecological succession, can influence genetics and viability of populations clearly dependent on those processes.[38]

A number of individuals or groups of species can serve as "early warning" indicators of ecosystem health. Presence and condition of microbiotic crusts on rangelands can act as indicators of soil properties and grazing effects. Impending problems of soil productivity can be indexed by tracking disruptions of soil processes, decreases in soil bacterial or fungal activity, decreases in soil fungal or bacterial biomass, change in the ratio of soil fungal to bacterial biomass, decreases in the number of soil protozoa, change in soil nematode numbers, and soil nematode community structure or maturity index. Butterflies and other invertebrate herbivores can help indicate general trends of total ecosystem diversity. Additional bioindicators can include selected macrofungi, lichens, and bryophytes (see Plants and Allies).

Research Information Needs

A first-ever catalogue of biodiversity of the Basin revealed diverse communities of plants, invertebrates, and vertebrates. However, many species groups are largely unstudied. During our process of collecting information on species for this assessment, particularly during the expert panel surveys, we catalogued areas of major scientific information gaps on each species. This information was constructed as an RDA (research, development, and application) database in Paradox. This database can be searched with key words on taxonomic groups or by subject to determine additional, species-specific information needs. Examples include information gaps on relations of species with livestock grazing, pesticides, timber harvest, and roads. Following is a summary of the major research information needs identified during this assessment.

Basic Systematics of Major Species Groups

Entire taxonomic groups, particularly many of the invertebrates, still require basic systematics research. Many species of arthropods, particularly canopy-dwelling forest arthropods and soil mesoinvertebrates, remain undescribed. About 86 percent of arthropods, 67 percent of fungi, and 51 percent of mollusk species estimated to occur in the Basin not have been studied, surveyed, or, in some cases, even identified. Much inventory and basic systematics work remains to be done on these groups. Soil microorganism groups and microbiotic (soil) crusts of the Basin, although critical for maintaining soil productivity, are poorly known and little studied.

Most of the soil microbiota of the Basin is undescribed. This biota includes viruses, bacteria, protozoa, rotifers, nematodes, and soil microfungi, as well as algae. Even though we consider such taxa as species groups, basic empirical work still is needed on taxonomy, diversity, and ecological roles of these species, particularly in how they aid soil productivity and maintain health of forest and rangeland ecosystems.

Monitoring for Population Status of Species and Health of Ecosystems

Basic information on population status of most species is lacking in the assessment area. While it is infeasible to expect monitoring studies on most, or even many, of the species known or projected to occur in the Basin, monitoring studies can be designed to focus on species groups and indicators of biodiversity and trophic health of ecological communities and ecosystems. In this way, both species and ecosystems would be addressed in a coherent, complementary manner. See the sections

[38]See footnote 37.

below for discussions pertinent to specific taxonomic groups. Certainly, continued coordination with other agencies and organizations on monitoring and research studies provides for greater efficiency.

Plants and Allies

Fungi—Inventory of fungi is likely needed with those species potentially rare but that may have been undersampled in the past. Owing to the ephemeral nature of the sporocarps and their strong dependence on abiotic factors, such as precipitation for spore production, fungal species community analysis requires 5 to 10 years of collecting to adequately and comprehensively inventory the species in any one area. We also have no data on how fungi populations shift or move through the soil matrix. In some cases, a particular fungal colony may take decades to migrate by way of hyphal growth. Thus, it seems reasonable to expect such inventories to be part of a broad-based and long-term survey rather than mandated prior to every land management activity.

Type locations of rare fungi could be protected in small, site-specific mycological preserves of varying size depending on habitat and life history of the species, until further inventories or studies determine the species' status.

Lichens—Baseline inventories and studies to document lichen species presence, abundance, biomass, habitat requirements, and geographic distribution are needed. Inventories of lichens may be added to other biological inventory efforts with mapped locations. Standardized methods for sampling forest epiphyte lichens are needed. Inventory data could be verified with voucher specimens deposited in herbaria. From this information, identification guides and annotated catalog for lichens in each physiographic region of the Basin can be developed.

Status survey reviews can be conducted for the rare lichen species. This information could be shared with the State Heritage Programs in each state to complement information from private and State lands. Conservation strategy plans can then be developed for rare species which conserve and enhance their populations.

Successional studies of lichens are needed, including establishment, diversity, and abundance of lichens in vegetation stands of various ages and in different plant associations, substrates, and vertical strata. Studies are also needed to determine lichen recovery after fires, and their dispersal patterns by species, by groups of species, and by forest types.

Monitoring and research plans can be developed to evaluate effects of forest and rangeland management practices, including timber harvesting and other silvicultural practices, livestock grazing, and recreation. Other topics that need study include:

- determination of the lichen species in retention trees by topographic position, tree symmetry, crown type, and aggregation of the retention trees;
- determining the effects and advantages of selecting leave trees that contain a diversity of lichen species;
- determining how lichens on retention trees act as centers of dispersal;
- determining nitrogen fixation rates of lichens in microbiotic crusts in different rangeland cover types;
- determining the quantity and nutrient content of lichen litter-fall in the forest cover types;
- addressing the role of lichen through-fall and litter-fall in the nutrient cycling and biomass production of the various types and ages of forests;
- determining and quantifying the rates at which small mammals (flying squirrels and red-backed voles) eat lichen litter-fall, and the role of lichens in the trophic dynamics of small mammals and their predators such as forest predators (for example, boreal owl);
- researching the role of lichens as habitat and food for forest invertebrates;

- effects of burns on lichen viability and recovery;
- basic systematics and taxonomic studies of the tumbleweed or vagrant ground lichens; and
- applied research on the management of tumbleweed or vagrant ground lichens and their role as forage for native pronghorn antelope.

Bryophytes—Specific localities, habitats, and research needs for areas of the seven states within the Basin are on file (TS 1995). The data for Nevada and Utah are scanty. Despite the fact that thousands of collections of bryophytes have been made in the Basin over the last 150 years, vast areas have not been collected systematically or at all. In particular, liverworts have been undercollected and chronically misidentified, and need careful attention in future work.

The rare taxa listed in appendix 5D could be sought throughout the study area to better determine distributions and abundance. The localities of the taxa listed in appendix 5D as occurring at the edge of their range (for example, species primarily of eastern North America) are important for study for their role in migration or as relictual areas.

Arid habitats of all types are undercollected throughout the Basin. These include desert, shrub-steppe, pinyon-juniper woodland, oak woodland, and ponderosa pine forest. The composition and function of soil crusts, while relatively well studied in the Great Basin, particularly in Utah, is virtually unknown in the Columbia River basin. Some general collecting has been done in a few areas, but the problem needs to be approached on a regional basis, studying crusts in different plant associations and on different soil types. The effects of livestock trampling should be included in any such studies.

Most of the issues centered on old-growth and late-successional forests, as identified in Thomas and others (1993), also apply to forested areas of the Basin and need not be repeated here. The greatest similarities in the bryophyte flora and relative biomass in such forests occur in the mesic forests of the so-called "maritime extension" area in Idaho and Montana. If this flora is to be managed for long-term commercial harvest, then regulation and monitoring would help ensure that rare or disjunct species are not being depleted, and that recruitment is adequate to sustain harvest levels. Ponderosa pine forests have few bryophytes as epiphytes or in the understory, but representative stands may be protected and managed correctly to maintain associated bryophytes.

Calcareous substrates provide habitat for a distinctive group of bryophyte species. A few calcium-rich areas have been collected, particularly in the northern Rocky Mountains and elsewhere in Idaho, but those of Oregon and Washington are poorly known and may need further work.

Mineral deposits, usually occurring in areas previously mined for gold, silver, copper, mercury, and other materials, often provide substrate for a distinctive group of bryophytes. While these areas have received some attention in the Rocky Mountains, other sites within the study area have not been surveyed adequately for these species. The same sulfides that provide suitable conditions for some bryophytes, especially in mine runoff, also pollute streams and groundwater for other organisms. Mine tailings and debris undoubtedly have increased suitable habitat for some of these species, which often select disturbed or barren soils.

Until recently, wetlands were ignored by land managers, and a good history of collecting in these sites is provided by only a few individuals. With the advent of wetland fill regulations and community classifications, these areas are receiving more attention and some taxa now thought rare should become more common. Included with these wetlands are bogs and fens, the latter occurring on calcium-rich sites, which have been poorly collected for bryophytes outside of the Rocky Mountain region. Effects on bryophytes from grazing in peatlands have received little attention in the Pacific Northwest, but observations suggest that bryophytes are severely affected by trampling, as noted in the wet soil group.

Flood plain habitats have received recent attention because of wetland and riparian protection. Thomas and others (1993) identified how important floodplains were for bryophyte species diversity, and how many species, particularly liverworts, were concentrated in old-growth forests occurring there. A similar situation exists in the Columbia River basin, especially in the "maritime extension" areas of Idaho and Montana, where species depend on shade, wet soils, logs and other organic debris, and humid microclimate. As with the aquatic and splash-zone species in streams, this group of species can be affected to some degree by land ownership patterns and adverse conditions originating upstream on non-Federal lands, although effects would be less pernicious because few of these species are in the stream channel. The effects of livestock trampling should be included in any such studies.

Geothermal areas are sometimes known for unusual assemblages of plants that survive outside of their normal distributional limits, because heated ground provides snow-free conditions and a longer growing season (Given 1980, Lange 1973). Although many bryophyte specimens were collected from hot springs in Idaho and Montana, none appears to be restricted to this habitat on a regional basis or to exhibit an unusual distributional pattern. Eversman (1990) found lichens to be absent from geyser areas, presumably because of particulate matter and sulfurous fumes from geysers, but the flora was more normal near thermal springs. More work needs to be done in these areas to better describe their effects on bryophytes.

Steep, narrow canyons and isolated gorges provide ideal conditions for bryophytes to persist in areas outside their normal distributional limits. Shade, moisture, and cold air drainage all contribute to unusual species being found in these areas, sometimes as relics from cooler periglacial climates. Effects from livestock and humans are often limited here because of restricted access. More work needs to be done to inventory such sites, particularly those with historical bryological collecting that can be used for comparative purposes to monitor changes in the flora.

Aquatic and splash-zone bryophytes are subject to the same effects described by Thomas and others (1993). In addition, galvanized culverts, like roof flashing, may be toxic to aquatic bryophytes and may diminish species diversity on some streams.[39]

Vascular Plants—Inventories are needed of rare plant species and unique plant communities to better determine distribution and potential sensitivity to land management activities. Type locations of plants known to be rare could be protected from ground-disturbing activities.

Both *in situ* and *ex situ* plant conservation measures need to be considered. *Ex situ* measures include storage of seeds and spores of rare plants in seed banks, and use of botanical gardens for maintaining off-site populations of rare and at-risk species.

Additional research information needs on vascular plants include:

- basic biology;
- reproductive biology;
- basic demographics;
- seed-bed ecology;
- interactions with weeds;
- interactions with seed predators or herbivores;
- disturbance ecology; and
- building computer aided applications for botany, including GIS and geographic databases.

The CRBFLORA database developed for this assessment represents only the beginning of what could be a much larger product. There is tremendous potential for this database to be used for additional analysis. An example of the potential for this kind of analysis was demonstrated by K. Urban (1995) in his analysis of Floristic Biodiversity of the Camas Ecosystem Analysis Area. Using a matrix database that contained 1,234 vascular plant species over seven plant association groups, Urban analyzed:

[39]Personal communication. 1995. David H. Wagner, independent contractor, Eugene, Oregon 97401.

- the number of vascular plant species presently occurring in the analysis area;
- a comparison of the floristic richness of the analysis areas with other areas on the Umatilla National Forest;
- ecological distributions and habitat affinities for the species within the plant association groups selected;
- the occurrence of historically listed or presently listed sensitive plant species;
- determination of other "at risk" plant species in the analysis area;
- a ratio of introduced to native species in the planning area;
- a list of noxious weeds; and
- the continued harvestability of a list of culturally significant plants.

Completion of the CRBFLORA database cataloging all vascular plants of the assessment area, would aid efforts in inventory and monitoring and could greatly aid in the determination of species at risk.

Invertebrates

Microorganisms—We do not suggest a species-specific approach to microorganism management. However, to better provide for productive and sustainable ecosystems, we would need to understand which bacteria and other microorganisms species groups are favored and which are impaired by management activities. This entails further study on determining which microorganism species groups are present in various grassland, shrubland, forest, and riparian settings; how the species groups are affected by management activities; and how changes in microorganism groups directly or indirectly affect diversity, productivity, and sustainability of resource production.

Predators—An adaptive management monitoring study could test the working hypothesis that management activities aimed at maintaining only general conditions of soil productivity would also adequately protect taxa or functional groups of soil invertebrates, particularly predators, and their ecological functions. Such working hypotheses could be tested by a set of monitoring activities.

Controlled management experiments are needed to determine the distribution, biology, and response to management activities of a few selected arthropod predator species chosen on the basis of rarity, presumed ecological importance, and/or sensitivity to particular management activities. These species could be studied within the context of controlled management experiments to assess how human activities influence their abundance and distribution. Effort also could be placed on understanding how management of forests influences the process of predation. This can be accomplished through a continuing inquiry on predator-prey relationships.

Pollinators—Sampling is needed in sandy environments for presence and abundance of pollinator species, particularly for endemic bee species and to determine effects of recreational vehicle use. Surveys would determine dunes with particularly high bee diversity and endemism. Off-road vehicle activity not only reduces floral resources necessary as a food resource for bees, but also destroys bee nests and potential nest sites. Because assemblages of pollinator species can vary markedly among sandy substrates, information on species presence and absence will indicate which dunes have particularly high bee diversity and endemism. A next step could be to monitor bee composition and abundance under various management regimes.

The intricate relations between arthropods and plants, as exemplified by flowering plant-pollinator interactions, highlight the need for parallel development of plant and invertebrate databases. A pollinator database has been initiated for the current project ARS, at the Bee Laboratory, Logan, Utah and many databases for both general and rare plants are being and have been compiled by a variety of agencies (also see previous section on CRBFLORA database below). These systems

need to be compatible to better aid our understanding of the relations between pollinators and flowering plants in the Basin.

To develop an understanding of basic life history and ecological characteristics of pollinators, relatively large-scale, controlled, and replicated studies are also needed. Information on breeding biology and pollinator behavior is needed to design reintroductions and to evaluate effects of exotic plant and pollinator species. For instance, knowledge of dispersal distances of a pollinator can help determine the size of the area in which habitats and host plant species could be provided and where effects of exotic species can be expected.

Grassland Herbivores—Studies examining the effect of range management practices on plant successional changes may be undertaken to more fully understand the effects of these activities on the associated insect herbivores. Responses of grassland herbivores to designated management systems could be assessed in a variety of habitat conditions.

Many options of grazing including rotation timing, intensity, spatial and temporal extent, and length of deferment, could be developed on a site-specific basis. Rather than studying all possible options, a few major factors could be evaluated on a variety of vegetation types. For instance, the effects of the season of grazing on vegetation regrowth, plant forage quality for grassland invertebrates herbivores, soil compaction, and soil nitrogen content need to be examined in various grassland types.

The implications of prescribed burning on plant and subsequent invertebrate diversity are unknown. Factors such as fire interval, intensity, duration, season, patchiness, and spatial extent need to be examined to determine their effects on plant community composition and diversity and abundance of invertebrate herbivore and predators.

Little is known about the competition of exotic weeds and most native rangeland plants, particularly with respect to renovation efforts. Proposed introductions of exotic organisms to control native pests need to be accompanied by research to determine the effect of the exotic in displacing other native species that perform the same function.

Given that insecticides are a tool in pest management, the ecotoxicology of these chemicals as affecting non-target invertebrates needs to be studied. Research must look beyond immediate effects on target species to long-term and residual effects of treatment on the whole fauna. This includes investigations of effects on breeding vertebrates and on bioaccumulation chemicals in the food chain.

Invertebrates can be used as sensitive measures of range and grassland health using an ensemble of species that, in a sense, would feel the pulse of the system. Selected species could be relatively easy to monitor and could represent various trophic levels. For instance, butterflies are a group that can be monitored visually by non-entomologists with relatively brief training (Hammond 1994). Harvester ants are another excellent species for monitoring as they occur throughout many parts of the food web.

Forest Herbivores—Needed, and generally lacking, is research on invertebrate herbivores in forests to examine long-term or beneficial effects of individual insect species, insect assemblages, and associated diseases (Huffaker and others 1984, Stark 1987).

The management of pest species may continue to warrant research due to the need to monitor and control species that threaten forest management objectives. The protection from bark beetle infestation of harvestable timber stands, as well as individual or groups of trees in campgrounds, historic sites, and riparian buffers are examples of resources that need to be protected against adverse damage by specific pest species. The development of hazard rating systems are a priority for a number of species including bark beetles and pests that damage tree regeneration.

Research and monitoring of forest herbivores can include population monitoring, control of pests such as bark beetles, the use of herbivore assemblages as bioindicators of forest health, and other topics. Adaptive management studies can monitor areas treated by different silviculture practices, particularly various intensities of forest thinning and salvage harvests, to help determine conditions under which insect-caused tree damage or mortality occur.

A monitoring program can entail sampling arthropod forest herbivores, particularly butterflies, to index localized and short-term changes in the environment from management practices. Butterflies would indicator total ecosystem diversity and other invertebrate herbivore groups afford similar opportunities to index important ecosystem functions or ecosystem diversity. (See the section on Invertebrates for more detail on selection of invertebrate bioindicators.)

Lastly, studies aimed at gaining a better understanding of the various ecosystem functions that forest herbivores perform are necessary. For instance, whereas it is known that herbivores provide a prey base for numerous arthropod and vertebrate predators, little is known about the specific dietary preferences of bats, birds, amphibians, and other predators on invertebrate herbivores. Likewise, the role of invertebrate herbivores in contributing to wildlife habitat is relatively unexplored. One opportunity that is beginning to be examined is the manipulation of bark beetles using semiochemicals to produce snags for wildlife. This type of research both expands our basic knowledge of invertebrate functions in forest ecosystems and lays the groundwork for further development of practical management tools.

Research and Monitoring Priorities for All Invertebrate Groups—The practice of ecosystem management has increased our awareness of the multitude of essential roles that invertebrates play, which encourages a broadening of the scope of invertebrate investigations beyond those only of forest insect pests. Studies are needed on invertebrate specialists in the context of the entire ecosystem to determine the extent to which their ecological functions influence structure and function of ecological communities and growth and production of desired plant and animal populations. Integrated qualitative and quantitative studies are needed on the role of invertebrates in organic matter decomposition and nutrient cycling, and in providing a food base for vertebrates.

Research on invertebrates, as on other facets of ecosystems, could benefit from integration of the applied science disciplines. For instance, invertebrate specialists could provide more useful results by studying species in the context of the entire ecosystem. Similarly, wildlife, plant, and other specialists could address vital functions that invertebrates provide, such as prey sources and nutrient cyclers. As applied to invertebrate research, adaptive management, where working hypotheses are tested and revised, would advance basic knowledge about both these organisms and the effects of management activities on their survival and function. Integrated research can also take advantage of the unique expertise and perspective of sundry agencies, universities, and other concerned groups.

Research Emphasis—Little information exists on the effects of management practices on invertebrates because the importance of these organisms' ecological functions have previously not been recognized. Much of the information we do have comes from related species from other geographical areas, which often have very different conditions. Accordingly, effective extrapolation is limited. To better understand the effects of management, we suggest that our "best guess or professional opinions" be considered as working hypotheses. In the context of adaptive management, the working hypotheses may be tested. A landscape-scale set of adaptive management "tests" could be considered.

Land managers could likely use tools such as stand hazard rating schemes (indexes of a forest stands' susceptibility to insect pest outbreak), predictive monitoring, and non-pesticide control methods (for example, semiochemical and biological control methods) that are the result of applied research. However, basic research, including studies

on basic biology and taxonomy, dispersal behavior, and natural enemies, lays the foundation for such products.

Because insects and other invertebrates constitute the bulk of the biosphere's faunal biomass, their function as a food source to many species of birds, reptiles, amphibians, and small mammals also deserves additional research attention. Invertebrates are found at all trophic levels (except primary producers) and, by virtue of their bewildering abundance, play a major role in nutrient flow through ecosystems. Also, their importance as decomposers is obvious but often overlooked.

Monitoring Emphasis—Short generation times and high reproductive potential make invertebrates excellent indicators and "early warning" organisms. In addition, they can yield information on effects of treatments on small spatial scales because of their limited dispersal capabilities which, in certain situations is down to less than one hectare. These factors, plus the ubiquitous nature of invertebrates in all habitats, their unsurpassed diversity, and immense contribution to the faunal biomass make invertebrates unique and useful bioindicators of ecosystem change.

Indicator taxa may be useful for monitoring changes resulting from management activities in two fundamentally different ways. First, their abundance or biomass may be an index or surrogate for a critical ecosystem function. As such, they indicate trends of, or effects on, entire functional groups of invertebrate species, rather than an individual component species. For instance, the ratio of total bacterivorous nematodes to fungivorous nematodes may reveal critical dynamics of how the decomposer microbial food web functions or is changed by management practices, but does not indicate trends of individual nematode species.

Second, the richness and diversity of invertebrates may serve as an index of total ecosystem diversity which may differ under various management activities. The abundance and distribution patterns of an individual uncommon species may indicate subtle changes in specific microenvironments of interest. For these studies, taxa are significant at a species-level of resolution, and to be useful on a general basis, must be amenable to this degree of taxonomic precision and sampling ease. For instance, total ant species richness may be a useful index of community diversity, whereas the presence of *Amblypone oregonense* may indicate undisturbed old-forest floor conditions. Thus, candidates for indicator status can include the most abundant, widespread and species-rich assemblages or the most habitat-constrained and thus, uncommon, individual species depending on the monitoring objectives.

The key to using invertebrates as bioindicators is practicality. Candidate taxa for monitoring should, in general, be:

- relatively well-known (in terms of the functional role they play in a community) and functionally important,
- species-rich (contain enough species to avoid statistical errors inherent in small numbers but not so rich as to overwhelm sampling protocols),
- amenable to capture or observation with standardized, low-technology techniques,
- common and widespread (see above for exceptions),
- relatively easy to identify (to an appropriate level of resolution, not necessarily to species), and
- relatively large and showy, when possible.

Vertebrates

Amphibians—Increased interest and concern regarding the effects of resource projects on amphibian distribution and abundance has resulted in increased awareness and inventory on Federal lands. Basic inventories are needed on most amphibian species. Survey protocols are being developed for Washington and Oregon (Cochran and Thomas 1995).

Research is needed on the effects of changes in water quality on larval stages of amphibians, influence of vegetation canopy on breeding ponds and streams (shading/sunlight ratios), and habitat used for dispersal. Studies of the influence on amphibians and habitats from eutrophication of water bodies and increases in ultraviolet radiation and acid precipitation need to be conducted as well.

Monitoring changes in vegetation cover type and structure may not be adequate to determine trends of amphibian population densities and distribution. Determining these parameters entails inventory and monitoring of specific substrates such as down wood, and microhabitat conditions such as deep, moist talus. Studies are also needed on effects on amphibian populations and habitats from livestock grazing and pesticide use.

Reptiles—Surveys for presence are needed of species that (1) currently seem to be patchily distributed with apparently disjunct populations, to determine occurrence in potentially unoccupied portions of their range; (2) species currently listed by agencies as sensitive but which may be more common or more widely distributed than originally reported; and (3) species that appear to be declining in parts of their range for unknown reasons. Survey should be conducted during optimal times of the day or night and in optimal habitats for specific species, such as night snakes and sharptail snakes.

Neotropical Migratory Birds—Research is needed on neotropical migratory birds to better understand environmental and habitat conditions affecting population trends. Continued monitoring, as through Breeding Bird Surveys and tracking trends of habitats, would provide useful information.

Other Birds—Studies are needed on effects of fire occurrence, fire suppression, season of burn, and changes of vegetation pattern resulting from burns and fire suppression on ground-nesting birds and their habitats. Other studies are needed on species-specific effects of livestock grazing, changes in distribution and density of nest parasites (brown cowbird), changes in insect populations, and availability of free water. Trends of arid-land raptors may deserve monitoring.

Bats—Basic inventories for presence and distribution are needed particularly for the more rare bat species. Key unknowns and research needs for bats include the effects of ectoparasites, pesticides, and timber removal. It is well known that parasites are present on bats but the effects are not well understood. The same is true for the effects of pesticides. Very little is known or understood regarding the effects of timber removal on bats. It is recognized that some species of bats use snags and other large trees, either the cavities or deep-furrowed bark, for roosting. However, it is not well understood how forest structures and landscape patterns around the snag or tree influences site selection by bats.

Carnivores—Further research is needed on current distribution of forest carnivores (American marten, fisher, lynx, and wolverine) and on their habitat requirements in terms of kinds, amounts, and arrangements of environments at multiple ecological scales and across all geographic regions of the Basin. For the same species, information is needed on the influence of sex, age, and social structure on habitat selection. Information also is needed on how these species respond to human-altered habitats (landscapes). Lastly, we need information on how habitat quality gradients affect dispersal rates, directions, and distances.

Other Mammals—Monitoring the status of populations of carnivores and ungulates (particularly those potentially impacted by livestock grazing activities) would provide use information for evaluating or guiding future activities.

Caveats

Overall, conducting evaluations on a broad geographic scale is difficult when additional, finer-grained information on populations and environments is not available. Because this is the first compilation of information over so vast a set of environments and taxonomic groups in the

Basin, several cautions in using and interpreting the information are in order. These include confidence in the information, inclusion of species, resolution of environmental data, use of expert rule sets, and limitations concerning species models and environmental correlates.

The first caution treated here deals with confidence in the species information. Most of the information compiled for this project did not come from empirical field experiments with controls and adequate sample sizes for statistical analysis; it came from surveys, personal observations from species experts, unpublished data of experts, and ongoing studies. Such information is reliable in that it came from among the best, often the only, local experts. However, because of the dearth of scientific studies on most species, experts often expressed only moderate to low confidence levels in how well species are scientifically understood. Also, as evidenced by the range of confidence scores among experts for given species, experts sometimes disagreed on the level of confidence they placed in scientific knowledge of individual species. Our panel approach attempted to ameliorate such differences by collecting the full array of knowledge among experts rather than by trying to reach consensus on information.

The species information in this study, particularly in the SER database, is imprecise on a local scale because it applies to a wide array of sites and habitats at the broadscale. None of the species considered in this assessment has been studied across the full range of habitats and environmental conditions present throughout the Basin. Of the species studies that are available, none has looked at the full array of key environmental correlates and key ecological functions. Also, few if any species studies rate as replicable, with controls; experimental manipulation; large sample sizes; empirical, validated relations; and peer review with publication in primary scientific journals. We expect that, over time, local information and well-designed studies can substantially improve at a finer resolution much of the broad-scale information we have gathered and broad-scale patterns we have deduced. However, some information, such as range-wide location data on rare plants and range maps of vertebrates, can only be produced at the broadscale.

A second caution is that limits of time and funding and the absence of prior comprehensive analyses of this type meant focusing the work for plants on listed and potentially at-risk species. For invertebrates, it meant describing an important but selected set of ecological functions of species groups and detailing information on only a small sampling of individual species. A fuller knowledge of vertebrates allowed us to address nearly all species. A thorough analysis, beyond the scope of this study, still needs to be done on the entire flora and on a broader invertebrate fauna of the Basin. For example, we have not described diversity and functions of parasitoids and parasites and of the many micropathogens present in the area. Disease and pathogenic effects may be critical factors limiting some plant and animal populations.

Much of the base information we used to gauge historical changes in habitats and species was developed at a broad scale using 1-square-kilometer resolution. This level of resolution is far too broad to identify patch- or site-specific conditions and substrates that are important to describing habitats for most plants and invertebrates. Our work must be seen as an initial step toward more site-specific evaluations.

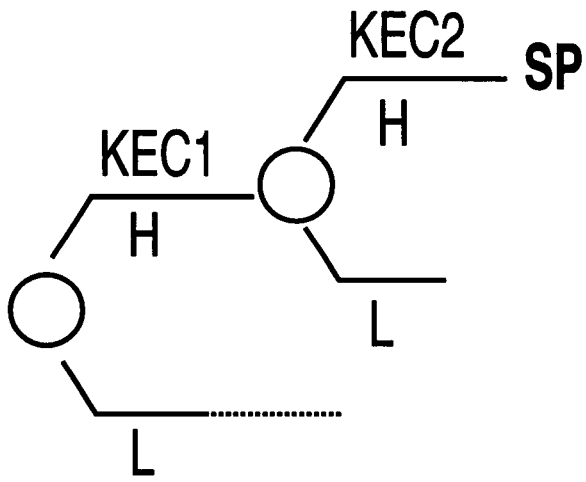
Essentially, the evaluations of the ecological relations between species and their environment presented in this chapter constitute expert rule sets. They can be further formalized as Bayesian models of species-environment relations by representing them as conditional probabilities, estimating the strength of those probabilities, and predicting potential outcomes in terms of population response. This is one approach to further depicting uncertainties and building a quantitative species model as a prelude to validation.

For example, for species thought to be vulnerable to specific management activities, a simple Bayesian belief network can be described as

P(Sp | KEC1, KEC2, ...), where P = probability of effects, Sp = species response (realized fitness, numerical response, or functional response), and KEC = key environmental correlate (fig. 5.11). KECs can take on various levels, most simply depicted as low (L) or high (H). One testable premise of this approach is that probabilities of levels of KECs are joint; that is, the species responds to the combination of all factors. By formalizing species information as conditional probabilities, specific hypotheses on species effects can be generated and tested through observation or experimental studies in the field.

Additional caveats pertaining to the species-environment relations information gathered for this study include the following. First, species models that should otherwise include a number of environmental correlates tend to "degenerate" into simple community (vegetation cover type and structural stage) models for three major reasons. (1) Many key environmental correlates were not fully quantified or specified for each species. Thus, the GIS models resulting from the SER database information must be considered "first generation" species models built at the wide geographic extent of the Basin. Also, correlates often were a combination of environmental associates and requirements. (2) GIS environmental correlates for species often were specified at a spatial resolution finer than that used in this broad-scale assessment. The current analysis (typically 1-km^2 resolution) lacks the GIS data at finer resolutions necessary to truly determine environments and effects for many sessile or small-bodied species. (3) The models cannot be fully specified at this time because of incomplete scientific knowledge. There is a basic lack of empirical data on species' environmental correlates.

Another reason why some of the key environmental correlates cannot be modeled in GIS at this time includes direction specified in contracts and expert panels to not necessarily tie descriptions of correlates only to available GIS themes and attributes. The purpose was to broaden our understanding of the kinds and levels of resolution of correlates needed to fully describe suitable environments for species, and not to be anchored by available data sets.



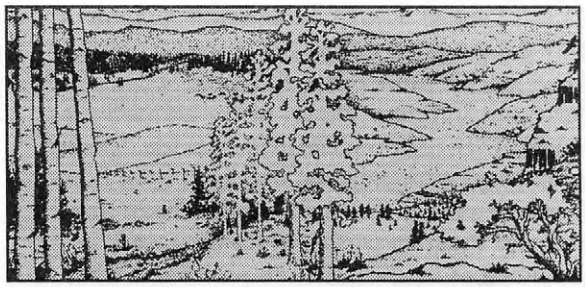


Figure 5.11— Schematic for a Bayesian belief model of species-environment relations. Circles denote potential conditions, such as a key environmental correlate (KEC) occurring with high probability (H) or low probability (L), ultimately affecting the overall likelihood of species presence (SP).

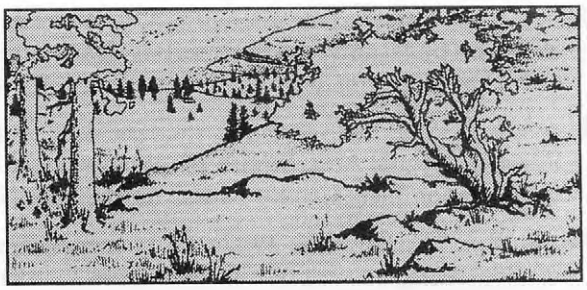
One result of not being able to model in GIS all key environmental correlates of species is that, at least for generalist species, potential habitat was grossly overestimated, particularly considering analyses not involving using the current species' range as a "mask" in the analysis. This is because many such models simplify to estimates of vegetation cover types and structural stages. Such analyses also tended to be insensitive to changes in environmental components represented poorly or not at all in the GIS models, such as snags, down wood, climatic factors, and human density. The solution is to develop more finer-grained GIS data for specific portions or habitats within the Basin, thereby explicitly representing these other unmodeled correlates in the species GIS models.

ACKNOWLEDGMENTS

We began this assessment with virtually no compiled information on the terrestrial biota of the Basin. We gratefully acknowledge the direct participation of a small army of contractors, panelists, and colleagues in helping to compile this first biodiversity catalogue and species assessment of this Basin (see appendix 5C). This is a necessarily incomplete beginning; for instance, invertebrate species are represented in the SER database as examples only, and plants include only federally listed or rare individual species and species groups. But it also serves to highlight next steps in further evaluations.

Herculean database support and programming was provided by Barbara Wales, Kevin Gutierrez, William Connelly, Michael Pitt, and Brian Platz.

We extend our appreciation to the following people who helped facilitate panels, scribe panel notes, and help in many other ways in the data collection processes. Plants: Kristin Buege, Teresa Catlin, Carolyn Close, Alexia Cochrane, Anne Dalton, Susan Erwin, Bruce Gibson, Doug Goldenberg, Katie Grenier, Diane Hildebrand, Darryl Inani, Leah King, Larry Loftis, Cynthia Persichetty-O'Hara, Faye Streier, Nancy Taylor-Grant, and Sherry Wood. Invertebrates: Bill Emmingham, Dianne Hildebrand, Sherm Karl, Steve Leonard, Iral Ragenovich, Kathy Sheehan, Keith Sprengel, and Beth Willhite. Vertebrates: Bill Gaines, Kathy Glass, George Halekas, Bill Otani, Susan Piper, Elaine Rybak, Sharon Selvaggio, Kaz Thea, Nancy Warren, Tammy West, and Elaine Zieroth. Data entry and interpretation: Leila Gibson, Karen Kronner, Barbara Lustig, Larry Richards, Patrick Shanley, Sally Sovey, Jenny Taylor, Kim Wassmuth, and Michelle Williams. Our gratitude to the vascular plant area coordinators: Kathy Ahlenslager, Jerry Hustafa, Catherine Jean, Amy Miller, Wayne Owen, Steve Shelly, and also Karl Urban, Maria Mantas and Richard Helliwell for their contributions to the vascular plant analysis. Also, see appendix 5C for names of plant and other species experts who participated directly in collecting, organizing, and analyzing information, and writing.



As well, we gratefully acknowledge the following for discussions, for contributing additional information, or for peer reviews of interim data sets and reports. Plants: Kathy Ahlenslager, Duane Atwood, Jane Belknap, Wong Shic Hong, Peter Lesica, Joy Mastrogiuseppe, Laura Potash, Tony Reznicek, Dave Wagner, and Robert Wooley reviewed documents; and Rene Belland, John Davis, Patricia Eckel, Joe Elliot, Nancy Fredricks, and Jimmy Kagan provided information and discussions. Invertebrates: Elaine Ingham and Jack Lattin provided information on species estimates. Vertebrates and/or general process: Rick Brown, David Cleaves, Richard Holthausen, Tim Max, Scott Mills, Rick Mishaga, Martin Raphael, Len Ruggiero, Fred Samson, Allan Thomas, Nancy Warren, and Michael Wisdom. We also appreciate the support of the FS and BLM regional and local office staffs throughout the Basin.

Chuck Lobdell, Kaz Thea, and others of the USFWS provided summary reports on federally listed species. Steve Fritts, Rob Hazelwood, Chris Servheen, and John Weaver of the USFWS provided advice on forest carnivore models. Species range maps were prepared with help from Rick Demmer and Jay Shepard. We also thank state Heritage Program personnel for their work in providing us location data on plants and other species. Chuck Harris of Idaho Department of Fish and Game provided coordination on species conservation strategies. Richard Helliwell provided text on native taxonomy of plant species of tribal concern.

Michael Wisdom acted as Terrestrial Staff Co-leader during the initial phases of the project; we thank him for his help in shaping the scope of the assessment.

We also are grateful to the authors and editors of the previous compendium on forest health issues in eastern Washington and Oregon edited by Rich Everett, Paul Hessburg, Mark Jensen, and Bernard Bormann (Everett and others 1993). We stand on their shoulders.

Technical reviews of the manuscript were provided by Allen Thomas of Bureau of Land Management, Boise, Idaho; Lisa Norris of Forest Service, Portland, Oregon; Paul Whitman of Bureau of Land Management, Lakeview, Oregon; and two anonymous ("blind peer") reviewers.

GLOSSARY

detritovory - Ingestion of detritus (dead or decaying organic matter)

disseminule - Seeds, spores, or other fruiting or vegetative parts of plants that serve to distribute species across space.

ecological process - A general description of species interactions, or transmission of substances, nutrients, or energy, throughout an ecosystem. An example is organic matter breakdown within, and incorporation into, soil.

ecological subsystem - A portion of an ecosystem identified by physical substrates and a unique assemblage of species and their ecological functions. An example is the tree canopy subsystem, as part of the terrestrial above-ground environments found within terrestrial forest ecosystems.

ectomycorrhizae - Species of (usually) thread-like fungus that binds onto roots of trees or other plants, that aid in nutrient uptake.

endemism and endemic species - Endemism refers to the condition in which a species is found only within a specific area and nowhere else. Endemic species were classified in the following categories:

locally endemic: Populations are restricted to a very small area (that is, one portion of a mountain range, one canyon, etc.) These taxa may also be restricted to highly specialized habitats. The range may lie entirely within, or on the assessment area boundary.

regionally endemic: Populations inhabit a larger geographic area than that of the local endemics (that is, southeast Oregon, the Palouse etc.) These species may also be closely associated with certain habitats, and their range may lie entirely within, or on the Assessment Area boundary.

peripheral: Populations lie on the margins of the assessment area boundary or in the case of some bird species, completely outside of the Basin. Birds such as the Pacific loon are casual visitors away from the normal species range.

disjunct: Populations in the assessment area are substantially separated geographically from the remainder of the species range.

scattered: Populations are sparsely distributed within the assessment area. In the case of birds this might indicate specialized habitats for wintering, migrating or breeding.

common: Not to be confused with abundance which refers to populations. Populations can be common but not have a large number of individuals. For example, mountain lion populations are probably common within the northwest. However, each population has a relatively small number of individuals. In contrast some species such as the spotted frog in eastern Oregon may have just a few scattered populations with many individuals in each population. The spotted frog would go into the scattered category.

environmental correlate - see key environmental correlate

ecological function - see key ecological function

expert panel - A gathering of scientific experts in species ecology, as used in this analysis to develop the species ecology databases. Expert panels were run for this analysis by the Terrestrial Staff, using a modified Delphi process, for collecting their knowledge and expertise on species ecology, key environmental correlates, key ecological functions, range distributions, and other information.

fitness - see realized fitness

hyphae - (hyphal, adj) - thread - like masses produced by some species of fungi, typically out of sight below ground or within decaying wood

key environmental correlate (KEC) - The set of habitat and other biological and physical attributes of an environment that most influences a given species' realized fitness (requirements) or that associate with species occurrences (associates). KECs include vegetation cover types (such as lodgepole pine forest), structural stages (such as open canopy stand), substrates (such as down wood), and other environmental factors not traditionally included in descriptions of species habitats (such as hunting pressure, proximity to urban areas, air quality, and trophic interactions with other species). Also see potentially suitable environment.

key ecological function (KEF) - The primary set of activities performed by organisms that affect the ecological function of their ecosystem. An example is decomposition of byproducts of decaying organic material (such as by the invertebrate *Argilophilus hammodi*), or creation of burrows (such as by American badger *Taxidea taxus*) that can be occupied by secondary burrow-users (such as longnose leopard lizard *Gambelia wislizenii*).

population viability - The likelihood of continued existence of a well-distributed population or species to a specified time period. For this analysis, the time period is 100 years. For example, high viability is a high likelihood of continued existence of well-distributed populations for a long time period (a century or longer).

population viability analysis (PVA) and population viability assessment or evaluation - The spatially-explicit, quantitative analysis and simulation modeling of a population and its environmental conditions over time under one or more management scenarios, typically to determine the likelihood of persistence of the population. Population viability is influenced by demographic, genetic, and environmental factors. When such factors are explicitly quantified and modeled, a true quantitative (sometimes called "hard-core") PVA is said to be conducted. When such factors are not quantified, such as by modeling only potentially suitable environments of a species over space and time, then population viability is only inferred. In this case, a "softer" population viability assessment or evaluation is said to be conducted.

potentially suitable environment - The full set of key environmental correlates (associates or requirements) for an individual species or species group. In this analysis, potentially suitable environments are mapped and their total area and spatial patterns are assessed, as one indicator of potential effects on population viability.

realized fitness - The vitality of offspring of animals or propagules of plants under actual conditions in the field. When a population is viable, it is at least able to replace itself, and the realized fitness of its individuals allow for continued reproduction over time.

saprophyte - An organism, including plants usually lacking chlorophyll, that lives off other decaying or dead plants.

symbiont - A species of plant or animal that lives closely associated (sometimes necessarily so) with another species.

APPENDIX 5A

Disposition of species groups in the terrestrial ecology staff database. (Many other species were additionally treated through contract reports, see appendix 5B for list.)

Species group	Individual species or species groups included in the Terrestrial Species-Environment Relations (SER) database
fungi	rare species are treated individually, as identified by Mike Castellano
lichens	functional groups of species, as identified by Roger Rosentreter
bryophytes	functional groups of species, as identified by John Christy
vascular plants	C1 and C2 candidate species treated individually; selected others by species lists or communities, as identified by expert panels, in contract reports, and the plant task group's leader, Lisa Croft, and staff
soil bacteria	general functional species groups, as identified in contract reports by Ingham (1995) and Muehlchen (1994)
soil protozoa	general functional species groups, as identified in contract report by Ingham (1995)
soil nematodes	general functional species groups, as identified in contract report by Ingham (1995)
soil rotifers	general functional species groups, as identified in contract report by Ingham (1995)
other invertebrates (arthropods)	single species as representatives of functional groups of species, as identified by contract reports and expert panels
vertebrates	all single species addressed

APPENDIX 5B

List of contract and internal reports provided for this assessment.[1]

Brainerd, Richard; Zika, Peter; Newhouse, Bruce [and others]. 1995. Biogeography of the Genus *Carex* in the Columbia River Basin and neighboring lands. A report to the U.S. Forest Service, Eastside Ecosystem Management Project; contract report; contract 43-0E00-5-5042. 58 p. + appendices.

Bunting, S.C.; Peters, E.F. 1994. Impact of fire management on rangelands of the intermountain west. Moscow ID: University of Idaho, Department of Range Resources. contract report; contract 43-0E00-4-9113. 24 p. + tables.

Burkhardt, J.W. 1994. Herbivory in the Intermountain West: an overview of evolutionary history, historic cultural impacts and lessons from the past. Indian Valley, ID. 49 p.

Burkhardt, J. Wayne. 1994. Paleoecological relationships of prehistoric *Equus* in the Intermountain West: An overview with implications for management of wild horses and burros. contract report; contract 43-0E00-4-9137. 49 p.

Castellano, Michael A. 1995. Report on Fungi. 75 p.

Christensen, Alan G.; Lyon, L. Jack; Pedersen, Richard [and others]. 1995. Ungulate assessment in the Columbia River Basin. 121 p.

Christy, J.A.; Harpel, J.S. 1995. Bryophytes of the Columbia River Basin (Draft). [Portland, OR]: Oregon Natural Heritage Program. contract report; contract 43-0E00-5-5358. 26 p. + appendices.

Clark, P.E. 1994. Livestock-big game interactions: a selected review with emphasis on literature from the interior Pacific Northwest. Corvallis, OR: Oregon State University, Department of Rangeland Resources. contract report; contract 43-0E00-4-9156. 94 p.

Diedrich, J.; Evenden, A.; Greene, S.; Harmon, D.; Petersen, M.; Sater, S. No date (1994). The role of natural areas in the Columbia River Basin assessment and planning. U.S. Department of Agriculture, Forest Service. 8 p. + table.

Eddleman, L.E.; Miller, R.F.; Miller, P.M.; Dysart, P.L. 1994. Western juniper woodlands (of the Pacific Northwest): science assessment. Corvallis, OR: Oregon State University, Department of Rangeland Resources. contract report; contract 43-0E00-4-9121. 131 p.

Eversman, S. [1995]. Lichens of the Yellowstone Ecosystem. Prepared for the East Side Project, Columbia River Basin Ecosystem Management Plan. Bozeman, MT: Montana State University. contract report; contract 43-0E00-4-9195. 93 p.

Fogel, R. [1994]. Fungi from the Columbia Basin deposited in the University of Michigan Herbarium (MICH). Ann Arbor, MI: University of Michigan Herbarium. contract report; contract 43-0E0-4-9227. 21 p. + appendices.

Frest, T.J.; Johannes, E.J. 1995. Interior Columbia Basin mollusk species of special concern. Prepared for: Interior Columbia Basin Ecosystem Management Project. Seattle, WA: Deixis. contract report; contract 43-0E00-4-9112. 274 p. + tables.

APPENDIX 5C

Lists of experts consulted for information on species ecology. Also see Acknowledgments for additional names, and appendix 5B for author names on contract reports and other submitted reports for this assessment.

Plants

Technical Contributors:
Michael Castellano, fungi, U.S. Department of Agriculture, Forest Service
John Christy, bryophytes, Oregon Natural Heritage Program
Roger Rosentreter, lichens, U.S. Department of Interior, Bureau of Land Management

Geographic Area Coordinators:
Kathy Ahlenslager, Okanogan, East Cascades North and Columbia Basin
Jerry Hustafa, Blue Mountains
Cathie Jean, East Cascades South, High Lava Plains, Basin and Range
Wayne Owen, Idaho, Wyoming, Nevada
J. Steven Shelly, Montana

Report Contractors:
Sharon Eversman, Montana State University
Robert Fogel, University of Michigan Herbarium
Ed Guerrant and Linda McMahan, Berry Botanic Garden
Sam Hammer, Boston University
Julie Kaltenecker, Boise State University
Bradd Kropp, Utah State University
Bruce McCune, Oregon State University
Dale McNeil, University of the Pacific
Robert Meinke, Oregon State University
Orson Miller, Virginia Polytech Institute
Steven Miller, University of Wyoming
Peter Rice, University of Montana
Bruce Ryan, University of Arizona
Nancy Weber, Oregon State University
Marcia Wicklow-Howard, Boise State University
Salix and Associates: Richard Brainerd, Manuela Huso, Bruce Newhouse, Barbara Wilson, Peter Zika

Authors or Contributors to Plant Task Group Reports:
Alma Hanson, U.S. Department of Agriculture, Forest Service
Richard Helliwell, U.S. Department of Agriculture, Forest Service
Leah King, U.S. Department of Agriculture, Forest Service
Maria Mantas, U.S. Department of Agriculture, Forest Service
Joy Mastrogiuseppe, U.S. Department of Agriculture, Forest Service, Washington State University
Amy Miller, U.S. Department of Agriculture, Forest Service
Karl Urban, U.S. Department of Agriculture, Forest Service

APPENDIX 5D

Taxa with five or fewer occurrences in the study area, categorized by endemic status, phytogeographical affinities, documented rarity or problem status. Taxa with more than 5 occurrences were included if they were well documented as rare. There is overlap in some categories depending on the taxon.

1. ENDEMIC TAXA

A. Western North America

These taxa are confined to the area in or west of the Rocky Mountains (Schofield 1984). Taxa with narrower endemism within the study area are listed separately in Sections B, C, and D.

Liverworts:
Frullania franciscana
Porella bolanderi
Riccia trichocarpa
Sphaerocarpos hians

Hornworts:
Phaeoceros hallii

Mosses:
Amphidium californicum
Anacolia menziesii var. baueri
Brachythecium bolanderi
Brachythecium holzingeri
Bryum calobryoides
Bryum gemmascens
Bryum meesioides Dendroalsia abietina
Dichodontium olympicum
Dicranum rhabdocarpum
Encalypta intermedia
Fissidens ventricosus
Homalothecium arenarium
Isothecium cristatum
Orthotrichum bolanderi
Orthotrichum praemorsum Pohlia bolanderi
Pohlia bolanderi var. *seriata*
Pohlia tundrae
Porotrichum vancouveriense
Pseudoleskea atricha
Pseudoleskea incurvata var. gigantea
Pseudoleskea radicosa var. denudata
Racomitrium brevipes
Racomitrium depressum
Racomitrium obesum
Racomitrium varium
Schistidium cinclidodonteum
Tripterocladium leucocladulum

B. Endemic to Northern or Central Rocky Mountains

Mosses:
Pseudoleskea incruvata var. *tenuiretis*
Pseudoleskea radicosa var. *pallida*

C. Endemic to Dry Intermountain Region ("Dry Interior")

Mosses:
Orthotrichum hallii
Orthotrichum holzingeri
Pseudocrossidium obtusulum
Pottia nevadensis

D. Endemic to interior Columbia River Basin

Mosses:
Bryoerythrophyllum columbianum
Grimmia brittoniae

2. MEDITERRANEAN CLIMATE IN WESTERN NORTH AMERICA

These taxa are confined to winter wet-summer dry climatic areas of the world (Schofield 1980, 1994). Those marked with an asterisk (*) are endemic to western North America as listed in Section 1.

Hornworts:
Phaeoceros hallii *

Liverworts:
Douinia ovata
Frullania franciscana *
Lunularia cruciata (a greenhouse weed in the interior Columbia River Basin)

Mosses:
Amphidium californicum *
Porotrichum vancouveriense
Claopodium whippleanum
Crumia latifolia
Dendroalsia abietina *
Desmatodon obtusifolius
Ditrichum ambiguum
Entosthodon fascicularis
Fissidens ventricosus *
Homalothecium arenarium *
Isothecium cristatum *
Racomitrium varium *
Timmiella crassinervis
Tortula laevipila
Tortula subulata

3. EASTERN NORTH AMERICA

These taxa are widespread east of the Rocky Mountains, and many have a circumpolar distribution. They occur mostly along the eastern edge of the Columbia River basin, at the western edge of their range (Schofield 1980).

Liverworts:

Blepharostoma trichophyllum ssp. *brevirete*
Calypogeia fissa ssp. *neogaea*
Calypogeia integristipula
Lophocolea bidentata
Pedinophyllum interruptum
Porella platyphylloidea

Mosses:

Amblystegium varium
Atrichum angustatum
Atrichum crispum
Barbula unguiculata
Brachythecium campestre
Brachythecium digastrum
Brachythecium oxycladon
Brachythecium populeum
Callicladium haldanianum
Campylium hispidulum
Climacium americanum
Cyrto-hypnum minutulum
Dicranella schreberiana var. *robusta*
Dicranum montanum
Dicranum viride
Herzogiella turfacea
Hygroamblystegium noterophilum
Hygroamblystegium tenax
Hypum imponens
Orthotrichum pumilum
Paraleucobryum longifolium
Philonotis fontana var. *caespitosa*
Philonotis muehlenbergii
Physcomitrium hookeri
Plagiomnium ciliare
Plagiomnium cuspidatum
Platygyrium repens
Pohlia elongata
Pohlia longicolla
Thuidium delicatulum
Tortella humilis
Tortula papillosa

4. Southern Arid Affinities

Taxa of more arid austral climates (Schofield 1980).

Liverworts:

Fossombronia longiseta
Mannia fragrans
Sphaerocarpos texanus

Mosses:

Brachythecium fendleri
Desmatodon plinthobius
Grimmia plagiopodia
Grimmia poecilostoma
Jaffueliobryum raui
Mnium arizonicum
Orthotrichum flowersii
Physcomitrium pygmaeum
Tortula bartramii

5. Circumpolar

Taxa with continuous arctic, boreal, or north temperate distributions, excluding those cited for eastern North America in Section 3. This list also excludes taxa with discontinuous distributions, which are cited in Section 6.

Liverworts:

Anthelia juratzkana
Apometzgeria pubescens
Asterella gracilis
Asterella lindenbergiana
Asterella saccata
Barbilophozia attenuata
Barbilophozia floerkei
Barbilophozia kunzeana
Barbilophozia quadriloba var. *quadriloba*
Bazzania tricrenata
Calypogeia neesiana
Calypogeia sphagnicola
Cephalozia catenulata
Cephalozia connivens
Cephaloziella elachista
Fossombronia foveolata
Gymnocolea inflata
Harpanthus flotovianus
Hygrobiella laxifolia
Jungermannia evansii
Jungermannia hyalina
Jungermannia obovata

Lophozia badensis
Lophozia latifolia
Lophozia opacifolia
Marsupella sphacelata
Marsupella ustulata
Metzgeria conjugata
Moerckia blyttii
Nardia breidleri
Nardia compressa
Nardia geoscyphus
Nardia scalaris
Pleuroclada albescens
Ptilidium ciliare
Riccardia chamedryfolia
Riccia cavernosa
Riccia fluitans
Riccia frostii
Riccia glauca
Scapania cuspiduligera var. *cuspiduligera*
Scapania paludicola
Tritomaria polita
Tritomaria quinquedentata var. *quinquedentata*

Mosses:
Aloina brevirostris
Amblyodon dealbatus
Arctoa fulvella
Brachythecium reflexum
Brachythecium turgidum
Bryum arcticum
Bryum calophyllum
Bryum cyclophyllum
Bryum pallens
Bryum schleicheri
Calliergon richardsonii
Calliergon trifarium
Campylium halleri
Campylium hispidulum
Campylium stellatum var. *protensum*
Catoscopium nigritum
Cirriphyllum cirrosum
Conostomum tetragonum
Desmatodon cernuus
Desmatodon leucostoma
Desmatodon systylium
Dicranella heteromalla

Dicranella palustris
Dicranella rufescens
Dicranella schreberiana
Dicranum acutifolium
Dicranum elongatum
Dicranum fragilifolium
Dicranum majus
Dicranum spadiceum
Didymodon asperifolius
Didymodon rigidulus var. *icmadophilus*
Didymodon tophaceus
Drepanocladus aduncus var. *polycarpus*
Drepanocladus fluitans
Eucladium verticillatum
Fissidens fontanus
Fissidens grandifrons
Fontinalis antipyretica var. *gigantea*
Grimmia trichophylla
Hypnum bambergeri
Hypnum pallescens
Hypnum pratense
Hypnum recurvatum
Hypnum vaucheri
Limprichtia revolvens
Meesia longiseta
Meesia triquetra
Meesia uliginosa
Myurella julacea
Myurella tenerrima
Orthothecium chryseum
Orthotrichum pylaisii
Orthotrichum speciosum
Oxystegus tenuirostris
Paludella squarrosa
Palustriella decipiens
Philonotis marchica
Plagiobryum demissum
Plagiobryum zieri
Plagiomnium drummondii
Plagiopus oederiana
Plagiothecium cavifolium
Platyhypnidium riparioides
Pogonatum dentatum
Pohlia atropurpurea
Pohlia bolanderi var. *seriata*
Pohlia filum

Pohlia ludwigii
Polytrichum commune var. *jensenii*
Polytrichum commune var. *perigoniale*
Polytrichum norvegicum
Pylaisiella polyantha
Racomitrium affine
Racomitrium fasciculare
Racomitrium lanuginosum
Rhytidium rugosum
Seligeria donniana
Scorpidium scorpioides
Sphagnum compactum
Sphagnum contortum
Sphagnum jensenii
Sphagnum platyphyllum
Sphagnum riparium
Sphagnum rubellum
Splachnum ampullaceum
Stegonia latifolia
Tayloria ligulata
Tayloria serrata
Tayloria splachnoides
Thuidium recognitum
Tortella arctica
Tortella tortelloides
Tortula muralis

6. Disjunct Distributions

These taxa represent disjunct elements found in Western North America, artifacts of discontinuous distribution patterns (Schofield 1969).

A. Bipolar

These taxa occur disjunctively at middle to high latitudes in both hemispheres and are absent in between.

Mosses:
Polytrichum formosum
Sphagnum palustre
Sphagnum subnitens

B. North Pacific

These taxa are distributed around the rim of the North Pacific Ocean, between north western North America and Japan. Some of the taxa extend inland to the Rocky Mountains (Schofield 1980).

Liverworts:
Blepharostoma arachnoideum
Frullania tamarisci ssp. *nisquallensis*
Radula bolanderi
Scapania bolanderi

Mosses:
Hypnum dieckii
Oligotrichum aligerum
Oligotrichum parallelum
Pogonatum contortum
Polytrichum sphaerothecium
Racomitrium muticum
Rhizomnium nudum

C. Humid Interior ("Maritime Extension", "Coastal Disjuncts")

These taxa are widely distributed west of the Cascade Mountains, and reappear in the Rocky Mountains. (Schofield 1976) Taxa with an asterisk (*) are endemic to Western North America, as listed in Section 1.

Mosses:
Dichodontium olympicum *
Ditrichum heteromallum
Hookeria lucens
Pseudotaxiphyllum elegans
Racomitrium brevipes *
Schistostega pennata
Tetraphis geniculata

D. Western North America and Western Europe

These taxa are mostly oceanic in distribution, with some occurring in alpine areas (Schofield 1969).

Mosses:
Bryum canariense
Bryum violaceum
Encalypta spathulata
Fabronia pusilla
Funaria muhlenbergii
Hygrohypnum alpinum
Hygrohypnum styriacum
Orthotrichum pulchellum
Orthotrichum striatum
Paraleucobryum enerve
Philonotis yezoana
Plagiothecium undulatum
Pottia lanceolata
Scleropodium cespitans
Tortula latifolia

E. Western North America and Eastern North America

Liverworts:
Diplophyllum obtusifolium

Mosses:
Buxbaumia aphylla
Heterocladium macounii
Neckera pennata
Pleuridium subulatum
Pohlia andalusica
Pohlia erecta
Tortella inclinata

F. Broken Circumpolar

These taxa occur in alpine areas within the Northern Hemisphere, but are absent from the arctic regions.

Liverworts:
Diplophylum albicans (suboceanic)

Mosses:
Andreaea nivalis
Buxbaumia aphylla
Campylopus fragilis
Crumia latifolia
Ditrichum ambiguum
Ditrichum pusillum
Encalypta affinis var. *macounii*
Hygrohypnum duriusclum
Hygrohypnum cochlearifolium
Hypnum procerrimum
Leskea polycarpa
Leskella nervosa
Pterogonium gracile
Schistidium pulvinatum
Schistidium tenerum
G. Circumalpine

Liverworts:
Anthelia julacea
Cephalozia leucantha
Gymnomitrion concinnatum
Gymnomitrion obtusum
Marsupella brevissima

Mosses:
Grimmia mollis
Oligotrichum hercynicum

7. Taxa Cited in the Literature as Rare in

North America

Hepaticae:
Blepharostoma arachnoideum (Schofield 1969)
Cephalozia lacinulata (Schuster 1974)
Pedinophyllum interruptum (Schuster 1980)
Scapania apiculata (Schuster 1974)
Scapania gymnostomophila (Godfrey 1977)

Mosses:

Brachythecium bolanderi (Lawton 1965)
Bruchia bolanderi (Rushing 1986)
Bryum gemmilucens (Spence 1988)
Calliergon trifarium (Crum and Anderson 1981)
Didymodon vinealis var. *nicholsonii* (McIntosh 1986)
Encalypta spathulata (Horton 1983)
Entosthodon fascicularis (Lawton 1971)
Grimmia brittoniae (Herman 1969)
Grimmia incurva (Crum and Anderson (1981)
Grimmia plagiopodia (Crum and Anderson 1981)
Hamatocaulis vernicosus (Lawton 1971)
Hygrohypnum cochlearifolium (Grout 1931)
Orthotrichum flowersii (Vitt 1973)
Orthotrichum holzingeri (Vitt 1991)
Pohlia andalusica (Shaw 1982)
Pohlia ludwigii (Shaw 1982)
Polytrichum sphaerothecium (Christy 1980)
Pottia lanceolata (Lawton 1971)
Pottia nevadensis (Lawton 1971)
Pseudocalliergon turgescens (Crum and Anderson 1981)
Pseudoleskea saviana (Lawton 1971)
Racomitrium aquaticum (Schofield 1976)
Splachnum sphaericum (Crum and Anderson 1981)
Tayloria acuminata (Crum and Anderson 1981)
Timmia norvegica (Crum and Anderson 1981)

8. PROBLEM TAXA

A. Species Concept Poorly Known

Liverworts and Hornworts:

Anthoceros fusiformis

Poorly segregated from *A. punctatus* (Frye and Clark 1947). Widespread and common in western Oregon. (Sanborn 1929). *Aspiromitus* (syn. *Anthoceros*) is a good species but Schuster (1992) does not give range information.

Lophozia wenzelii

"Much confused with other species, thus the range is poorly known". In western North America reported from Alaska and the Yukon. (Schuster 1969)

Mosses:

Atrichum hausknechtii

"Paroicous specimens of western North America, Japan and Europe can be put into *Atrichum undulatum* var. *gracilisetum*" (Crum and Anderson 1981). May be rare in North America, need to determine the chromosome number for this species (Noguchi and Osada 1960)

Brachythecium reflexum var. *pacificum*

Lawton (1971) stated that *B. reflexum* is rare in the western US, and called this species *B. reflexum* var. *pacificum*. According to Crum and Anderson (1981), this variety probably belongs to *B. reflexum*.

Bryum uliginosum

"A poorly known species". (Spence 1988)

Fissidens hallianus

Crum and Anderson (1981) did not feel that this taxon is genetically distinct from *Fissidens fontanus*.

Fissidens taxifolius

This is an eastern species. Most western material was referred by Pursell (1976) to *Fissidens aphelotaxifolius*.

Funaria americana

"Of scattered occurrence in the continental interior, especially in the prairie states." Lawton's wider range may be attributed to nomenclature confusion with *F. muhlenbergii* (Crum and Anderson 1981).

Gymnostomum calcareum

Zander (1977) combined this taxon with *G. aeruginosum*, but it is still recognized by Anderson and others (1990).

Orthotrichum palousense

There is no record of this species in Vitt (1973). Iit is probably an unpublished herbarium name.

Rhytidadelphus subpinnatus

This taxon was placed in *R. squarrosus* by Anderson and others (1990). Some feel that it is a valid species (Koponen 1971, 1975).

Sphagnum recurvum

"The complete range is somewhat uncertain owing to a confusion of taxonomic concepts" (Crum 1984).

B. Taxa Needing Verification, And If Correct Would Represent A Significant Range Extension:

Liverworts:

Barbilophozia atlantica

A high elevation taxon in New England, Great Lakes and in the Hudson Bay area (Schuster 1969). Unlikely in the Columbia River Basin (Personal communication. 1995. W.B. Schofield).

Cephalozia bicuspidata var. *ambigua*

An arctic-alpine species, the American distributions are poorly known. In Alaska and in a few high latitudes eastern locations (Schuster 1974).

Cephalozia bicuspidata var. *lammersiana*
Poorly known in North America, Schuster (1974) is skeptical of the reports from western North America.

Cephalozia loitlesbergeri
Found in southern and middle California, disjunct in Texas, Oklahoma, Kansas, Arkansas, and Louisiana (Schuster 1992).

Jungermannia gracillima
A holoarctic taxon restricted to the eastern half of the North American continent (Schuster 1974).

Jungermannia polaris
Generally a rather rare and sporadic taxon with an arctic-alpine distribution, known from alpine British Columbia sites and doubtful from Alberta (Schuster 1969). Doubtful in the Columbia River Basin (Personal communication. 1995. W.B. Schofield).

Odontoschisma sphagni
Rare and very localized in eastern North America with prior taxonomic problems (Schuster 1974). Poorly documented in Western North America (Personal communication. 1995. W.B. Schofield).

Riccia campbelliana
A northern taxon restricted in range in eastern North America, so unknown from the west (Schuster 1974).

Mosses:

Anomodon viticulosus
An eastern species (Crum and Anderson 1981).

Bartramia stricta
Probably based on an unusual morph of *B. ithyphylla* (Personal communication. 1995. W.B. Schofield).

Brachythecium calcareum
An endemic eastern North American taxon with disjuncts in Alaska, British Columbia and the Yukon Territory (Ireland 1982).

Campylopus schimperi
Mostly in northern sections of eastern North America. The only western records are from Alaska, the Yukon, and the Queen Charlotte Islands (Crum and Anderson 1981).

Cynodontium polycarpon
"May not even occur on this continent. We have seen only one North American collection correctly named... from the Lake Superior region (Crum and Anderson 1981).

Dicranum angustum
A circumpolar, subalpine-alpine taxon from Alaska and northern North America only (Persson and Holme 1961, Persson 1952).

Didymodon fallax var. *reflexus*
A circumtemperate taxon, rare in British Columbia (McIntosh 1986).

Drepanocladus brevifolius
An arctic-alpine taxon from the Rocky Mountains of Alberta; also Alaska and Greenland (Lawton 1971).

Grimmia pulvinata var. *africana*
This species "is extracted from *Grimmia orbicularis, Grimmia decipiens,* includes *Grimmia leibergii*" (Sayre 1952).

Grimmia unicolor

An eastern taxon, "records from British Columbia and Washington are presumed to be incorrect" (Crum and Anderson 1981).

Orthotrichum sordidum

Very common in the east and disjunct in Alaska (Vitt 1973).

Pottia crinita

A maritime European taxon found on moist banks (Smith 1978). On sea coasts, on rocks and banks in England (Dixon 1954).

Pottia intermedia

William's (1966) reported the first North American location as Ontario, Canada. Zander (1993) combined this into *Tortula intermedia*. It is often confused with other *Pottias*.

Ptychomitrium polyphyllum

Rare, more common in western most Norway and eastern Europe and Macaronesia, no North American sites listed (Nyholm 1960). Not listed by Anderson and others (1990).

Rhodobryum ontariense

Sporadic from Newfoundland to Alberta, south to North Carolina (Ireland 1982). This is the eastern species of *Rhodobryum*, while the *R. roseum* is found in the west, but rarely west of the Rocky Mountain (Personal communication. 1995. W.B. Schofield).

Rhodobryum roseum

Crum and Anderson (1981) considered the differences between *R. ontariense* and *R. roseum* "trivial and troublesome," and because the ranges overlap they use *R. roseum* for their plants. It is found in Alberta, Alaska and British Columbia. Schofield (Personal communication. 1995) feels that this is the western taxon.

Schistidium maritimum

A maritime taxon found along both coastal eastern and western North America (Crum and Anderson 1981).

Sphagnum fallax

This species Is apparently completely absent from the northern Rocky Mountains (Andrus and Layser 1976).

Sphagnum lescurii

An Amphiatlantic, eastern North American taxon with unclear distribution details due to the similarity between this and other related species (Andrus 1980). Crum (1984) put this species into *Sphagnum subsecundum* var. *rufescens*.

Sphagnum tenellum

An eastern taxon that also occurs in southeast Alaska and British Columbia (Crum 1984). Andrus (1980) gave the western distribution as along the Pacific Coast from Alaska to Vancouver Island, British Columbia.

Thamnobryum alleghaniense

An eastern taxon (Crum and Anderson 1981).

Timmiella anomala

A southwestern US taxon. Rrecords from Washington and British Columbia "appear to be *Timmiella crassinervis*" (Crum and Anderson 1981).

Tortula laevipila

An epiphytic taxon, Foster's Wallula collection is not very likely. The locations within the Columbia River Gorge region are probably correctly identified.

Ulota phyllantha

A maritime taxon found along both coastal eastern and western North America (Crum and Anderson 1981).

C. Taxa That Are No Longer Valid, Or Are Probably Misidentified:

Mosses:

Brachythecium acutum

Excluded from North America (Crum and Anderson 1981).

Brachythecium erythrorrhizon var. *thedenii*

Excluded from North America (Crum and Anderson 1981).

Brachythecium glareosum

Not considered a rare taxon in the assessment area, because there are 12 records. Excluded from North America (Anderson and others 1990).

Cynodontium gracilescens

Excluded from North America (Crum and Anderson 1981).

Distichium capillaceum var. *compactum*

Excluded from North America (Anderson and others 1990).

Hygrohypnum obtusifolium

This is probably a typographical error, and the name does not exist in the literature. It is probably *Scleropodium obtusifolium.*

Macrocoma sullivantii

Dale Vitt (Personal communication. 1995.) noted that this species of the southeastern United States was reported from Wyoming in error, resulting from a mix-up in specimen label data. The collection noted in error was actually *Orthotrichum rupestre.*

Plagiomnium affine

Excluded from North America (Anderson and others 1990).

Pohlia rothii var. *compacta*

Placed into *Pohlia andalusica* (Shaw 1981).

APPENDIX 5E

Neotropical migratory landbirds in the Columbia River Basin for which Breeding Bird Survey sample size is sufficient (recorded on ≥14 routes) to quantify significant long-term declines or increases in population trends, over 10-year and 26-year periods. Numbers in table are percent changes of populations over the time periods shown.

		Decline		Increase	
Species	**Nest Layer[1]**	**26 yr**	**10 yr**	**26 yr**	**10 yr**
		percent change in population			
Osprey	CA				6.4***
Red-tailed Hawk	CA			4.3***	4.0**
Golden Eagle	CA				10.9**
Killdeer	GR	-4.3***	-10.5***		
Long-billed Curlew	GR			5.1***	
Mourning Dove	SH	-2.2***			
Red-naped Sapsucker	CA			12.0*	
Calliope Hummingbird	CA		-13.4*		
Olive-sided Flycatcher	CA	-2.9**	-4.2**		
Willow Flycatcher	SH	-2.5**	-4.3***		
Gray Flycatcher	SH				13.6**
Say's Phoebe	CA			5.4*	
Horned Lark	GR	-2.9**			
Cliff Swallow	CA			2.8***	
House Wren	CA			4.4**	5.7*
Marsh Wren	SH				8.8*
Mountain Bluebird	CA			4.0***	8.1**
American Robin	CA		-1.5*		
Gray Catbird	SH			4.0**	6.3***
Loggerhead Shrike[2]	SH	-2.7**			
Warbling Vireo	CA			4.1**	
Orange-crowned Warbler	GR			3.5*	7.5**
Yellow Warbler	SH		-2.1**		
Townsend's Warbler	CA			5.2***	
Common Yellowthroat	SH				2.8*
Black-headed Grosbeak	SH			4.8***	5.4***
Rufous-sided Towhee	GR			3.5*	7.6***
Chipping Sparrow	SH	-2.7***			
Brewer's Sparrow	SH	-1.3***	-4.3***		
Lark Sparrow	SH	-2.9**			
Savannah Sparrow	GR		-3.2*		
Song Sparrow	SH	-2.7***			
Red-winged Blackbird	SH	-1.5*	2.3*		
Western Meadowlark	GR	-0.8*	-3.7***		
Brewer's Blackbird	SH	-1.3*	-4.3***		
Pine Siskin	CA		8.8***		
American Goldfinch	CA	-2.1*			

*: $P < 0.10$

**: $P < 0.05$

***: $P < 0.01$

[1] Nest-layer abbreviations: CA=subcanopy/canopy-nesting species; GR=ground-nesting species; SH=shrub-nesting species, based on characteristics described by Ehrlich and others (1988) and Martin (1993).

[2] Federal candidate (Category 2) for listing under the Endangered Species Act.

APPENDIX 5F

Key environmental correlates (KECs)for all species in the Species-Environment Relations (SER) database. The numbered codes in this classification correspond to codes denoted for each species in the SER database.

1 **Vegetation elements**
- 1.1 cover types (Society of American Forests, Society of Range Management, ICBEMP)
- 1.2 structural stages
  - 1.2.1 SAF stages
  - 1.2.2 SRM stages
  - 1.2.3 CRB stages
  - 1.2.4 Other stages used to denote plant response
    - 1.2.4.1 regeneration cut
    - 1.2.4.2 selectively logged
    - 1.2.4.3 thinned
    - 1.2.4.4 patch clearcut
    - 1.2.4.5 shelterwood
    - 1.2.4.6 overstory removal
- 1.3 forest or woodland vegetation substrates
  - 1.3.1 down wood (includes coarse woody debris, "CWD")
    - 1.3.1.1 down wood in riparian zone
  - 1.3.2 snags (entire tree dead)
    - 1.3.2.1 bark piles at base of snag
  - 1.3.3 mistletoe brooms
  - 1.3.4 litter
  - 1.3.5 duff
  - 1.3.6 shrubs
  - 1.3.7 fruits/seeds/mast
    - 1.3.7.1 seed caching
  - 1.3.8 dead parts of live trees
  - 1.3.9 moss
  - 1.3.10 trees
    - 1.3.10.1 exfoliating bark
  - 1.3.11 flowers
  - 1.3.12 lichens
  - 1.3.13 bark
  - 1.3.14 forbs (grass)
  - 1.3.15 cactus
  - 1.3.16 fungi
  - 1.3.17 roots, tubers, underground plant parts
  - 1.3.18 peatlands
- 1.4 herbaceous vegetation elements or substrates
  - 1.4.1 herbaceous vegetation cover
    - 1.4.1.1 aquatic submergent vegetation
  - 1.4.2 fruits/seeds
  - 1.4.3 moss
  - 1.4.4 cactus
  - 1.4.5 flowers
  - 1.4.6 shrubs
  - 1.4.7 fungi
  - 1.4.8 forbs

- 1.4.9 bulbs/tubers
- 1.4.10 cryptogamic crusts
- 1.5 diversity of vegetation cover types
- 1.6 edges
  - 1.6.1 openings
  - 1.6.2 meadows
- 1.7 mycorrhizal associations

2 Biological (non-vegetation) elements

- 2.1 presence of prey species (including small mammals, insects, birds, other spp.)
  - 2.1.1 carrion
- 2.2 presence of predators
  - 2.2.1 absence of predator
- 2.3 presence of exotic species
  - 2.3.1 exotic plants
  - 2.3.2 exotic animals
- 2.4 insect irruption areas
  - 2.4.1 mountain pine beetle
  - 2.4.2 spruce budworm
  - 2.4.3 gypsy moth
- 2.5 presence of burrows or presence of burrowing mammals
- 2.6 grazing
  - 2.6.1 direct effects (trample, consumed)
  - 2.6.2 indirect effects (habitat degradation)
  - 2.6.3 seasonality of grazing
- 2.7 presence of beaver or muskrat ponds or lodges
- 2.8 presence of nesting structures
  - 2.8.1 cavities
  - 2.8.2 platforms
- 2.9 presence of other species
  - 2.9.1 positive or neutral effect
  - 2.9.2 negative effect
- 2.10 forest pathogens
- 2.11 colonial nester

3 Non-vegetation terrestrial substrates

- 3.1 rocks
  - 3.1.1 gravel
- 3.2 soils
  - 3.2.1 soil class
  - 3.2.2 soil depth
  - 3.2.3 soil texture
    - 3.2.3.1 sand/dunes
    - 3.2.3.2 soil suitable for burrowing vertebrates
    - 3.2.3.3 soil suitable for burrowing invertebrates
  - 3.2.4 soil pH
  - 3.2.5 soil temperature
  - 3.2.6 soil moisture
  - 3.2.7 soil chemistry
  - 3.2.8 soil organic matter
- 3.3 lithic (rock) substrates
  - 3.3.1 lithic series or types (including lithic formations such as Jefferson limestone)
    - 3.3.1.1 granite
    - 3.3.1.2 basalt
    - 3.3.1.3 rhyolite

3.3.1.4 sedimentary and metamorphic (fine grained rock), including limestone
3.3.1.5 calcareous rock
3.3.1.6 serpentine
3.3.1.7 sand (sandstone)
3.3.1.8 clay (alluvium)
3.3.1.9 glacial till and landslides
3.3.1.10 playa (alkaline, saline)
3.3.1.11 tuff (volcanic ash)
3.3.1.12 metal rich
3.3.1.13 pumice

3.3.2 avalanche chute
3.3.3 cliff
3.3.4 talus
3.3.5 boulder, large rocks
3.3.6 cave
3.3.7 rock outcrops/crevices
3.3.8 lava flows
3.3.9 [blank]
3.3.10 lava tubes
3.3.11 canyons
3.3.12 barren ground
3.3.13 rugged terrain
3.3.14 rocky ridges
3.3.15 ravine
3.3.16 cirque or basins (also see entry 5.7 below)

3.4 snow
3.4.1 snow depth (winter)
3.4.2 glaciers, snow fields

3.5 water characteristics
3.5.1 dissolved oxygen
3.5.2 water depth
3.5.3 dissolved solids
3.5.4 water pH
3.5.5 water temperature
3.5.6 water velocity
3.5.7 water turbidity

3.6 forages above tree canopy

4 Riparian and aquatic bodies

4.1 rivers
4.1.1 riverine wetlands
4.1.2 oxbows

4.2 streams (permanent or seasonal)
4.2.1 intermittant
4.2.2 rocks in streams

4.3 seeps or springs (including warm seeps or springs)
4.4 exposed mudflats, sand bars
4.5 sand bars, unconsolidated shore
4.6 gravel bars
4.7 shallow water
4.8 lakes or reservoirs (lacustrine)
4.8.1 lakes with submergent vegetation
4.8.2 lakes with floating mats
4.8.3 lakes with silt or mud bottom
4.8.4 lakes with emergent vegetation

4.8.5 alkaline lake beds
4.9 ponds (permanent or seasonal)
4.9.1 ponds with submergent vegetation
4.9.2 ponds with floating mats
4.9.3 ponds with silt or mud bottoms
4.9.4 ponds with emergent vegetation
4.10 wetlands, marshes, or wet meadows (palustrine)
4.10.1 bulbs or tubers in wetlands, marshes, or wet meadows
4.10.2 Phragmites
4.11 bogs or fens
4.12 swamps
4.13 islands
4.14 waterfalls
4.15 hyporheic zone
4.16 irrigation ditches
4.17 ephemeral pools
4.18 deciduous riparian, including willow and cottonwood
4.19 vernal or seasonal flooding or flood plains
4.20 bottomlands
4.21 water table

5 Topographic or physiographic elements
5.1 elevation
5.2 slope
5.3 aspect
5.4 slope position
5.5 ridge tops
5.6 plateau
5.7 convex or concave basin (also see entry 3.3.16 above)
5.8 flat
5.9 mima

6 Climate
6.1 precipitation (amount, pattern, seasonality)
6.2 Mediterranean influence (dry summers)
6.3 maritime influence (higher humidity and more moisture)
6.4 temperature
6.5 humidity
6.6 wind

7 Fire
7.1 recency
7.1.1 recent fire
7.1.2 old fire
7.2 effects of fire suppression activities
7.2.1 positive effect
7.2.2 negative effect
7.2.3 neutral effect
7.3 fire frequency
7.3.1 positive effect
7.3.2 negative effect
7.3.3 neutral effect
7.4 fire intensity
7.4.1 overstory lethal
7.4.1.1 positive effect
7.4.1.2 negative effect

7.4.1.3 neutral effect
7.4.2 overstory non-lethal
7.4.2.1 positive effect
7.4.2.2 negative effect
7.4.2.3 neutral effect
7.5 prescribed fire
7.5.1 spring prescribed fire
7.5.1.1 positive effect
7.5.1.2 negative effect
7.5.1.3 neutral effect
7.5.2 late summer or fall prescribed fire
7.5.2.1 positive effect
7.5.2.2 negative effect
7.5.2.3 neutral effect
7.6 historic fire suppression
7.6.1 positive effect
7.6.2 negative effect
7.6.3 neutral effect

8 Human disturbance elements

8.1 recreation areas and activities (including dispersed camping areas)
8.1.1 positive effect
8.1.2 negative effect
8.2 roads or trails
8.2.1 positive effect
8.2.2 negative effect
8.3 residential development
8.3.1 positive effect
8.3.2 negative effect
8.4 buildings
8.4.1 positive effect
8.4.2 negative effect
8.5 bridges
8.5.1 positive effect
8.5.2 negative effect
8.6 tunnels (for mines, see above under Non-vegetation terrestrial substrates)
8.6.1 positive effect
8.6.2 negative effect
8.7 agriculture and croplands
8.7.1 positive effect
8.7.2 negative effect
8.8 livestock (disease)
8.8.1 positive effect
8.8.2 negative effect
8.9 mines and mining activities
8.9.1 positive effect
8.9.2 negative effect
8.9.3 neutral effect
8.10 harvest (including legal hunting, legal trapping, and illegal poaching of animals)
8.10.1 positive effect
8.10.2 negative effect
8.11 fences
8.11.1 positive effect
8.11.2 negative effect
8.12 bird feeders

8.12.1 positive effect
8.12.2 negative effect

8.13 winter recreation
8.13.1 positive effect
8.13.2 negative effect

8.14 garbage
8.14.1 positive effect
8.14.2 negative effect

8.15 logging
8.15.1 positive effect
8.15.2 negative effect

8.16 nest box
8.16.1 positive effect
8.16.2 negative effect

8.17 perch structures
8.17.1 positive effect
8.17.2 negative effect

8.18 platforms
8.18.1 positive effect
8.18.2 negative effect

8.19 guzzlers
8.19.1 positive effect
8.19.2 negative effect

8.20 pesticide use

8.21 exotic plant effects
8.21.1 direct displacement
8.21.2 indirect competition
8.21.3 inhibit recruitment
8.21.4 habitat structure change

8.22 livestock grazing strategies
8.22.1 season-long
8.22.1.1 positive effect
8.22.1.2 negative effect
8.22.1.3 neutral effect
8.22.2 spring grazing
8.22.2.1 positive effect
8.22.2.2 negative effect
8.22.2.3 neutral effect
8.22.3 summer grazing
8.22.3.1 positive effect
8.22.3.2 negative effect
8.22.3.3 neutral effect
8.22.4 fall grazing
8.22.4.1 positive effect
8.22.4.2 negative effect
8.22.4.3 neutral effect

9 Barriers to movement
9.1 forest management (clearcuts)
9.2 canopy closure
9.3 agriculture

10 Natural disturbance -- floods, scouring, openings in forests

APPENDIX 5G

Key ecological functions (KEFs) of all species in the Species-Environment Relations (SER) database. The numbered codes in this classification correspond to codes denoted for each species in the SER database.

1 **Trophic relations**
- 1.1 primary producer (chlorophyllous vascular plants)
  - 1.1.1 autotrophic (fully independent chlorophyllous plants)
  - 1.1.2 hemiparasitic (chlorophyllous plants that also partially derive nutrients via attachment to other chlorophyllous plants)
- 1.2 heterotrophic consumer
  - 1.2.1 primary consumer (herbivore) (also see below under Herbivory)
    - 1.2.1.1 foliovore (leaf-eater)
    - 1.2.1.2 spermivore (seed-eater)
    - 1.2.1.3 browser
    - 1.2.1.4 grazer
    - 1.2.1.5 frugivore (fruit eater)
    - 1.2.1.6 sap feeding (sucking insects)
    - 1.2.1.7 root feeders (invertebrates)
    - 1.2.1.8 sequesters plant metabolites
  - 1.2.2 secondary consumer (primary predator or carnivore)
    - 1.2.2.1 consumer or predator of invertebrates, potentially including insects (insectivorous)
    - 1.2.2.2 consumer or predator of vertebrates (other species than itself)
  - 1.2.3 tertiary consumer (secondary predator or carnivore)
    - 1.2.3.1 consumer of soil microorganisms
  - 1.2.4 largely omnivorous (plants and animals consumed)
  - 1.2.5 carrion feeder
  - 1.2.6 cannibalistic
  - 1.2.7 coprophagous (feeds on fecal material)
  - 1.2.8 aquatic herbivore (invertebrates)
  - 1.2.9 feeds in water on algae, ooze, and plankton (invertebrates)
- 1.3 achlorophyllous vascular plants (see 1.9 below for nonvasculars)
  - 1.3.1 mycotrophic (indirectly parasitic, non-green plants that derive nutrients from mycorrhizal fungi that are also associated with a chlorophyllous species that serves as the indirect host)
  - 1.3.2 saprophytic (derive nutrients from decaying organic matter via mycorrhizal fungi)
  - 1.3.3 parasitic (derive nutrients via direct attachment to chlorophyllous plants)
    - 1.3.3.1 root parasites
    - 1.3.3.2 stem parasites
- 1.4 detritivore (feeds directly on dead organic material)
- 1.5 decomposer (feeds on byproducts of decaying organic material)
- 1.6 commutator (chewing insects, typically on wood or vegetation)
- 1.7 forage or prey relations
  - 1.7.1 forage for animals
  - 1.7.2 prey for secondary or tertiary consumer (primary or secondary predator or carnivore)
  - 1.7.3 carrion source
  - 1.7.4 forage for invertebrates
- 1.8 major biomass
- 1.9 achlorophyllous non-vascular plants (see 1.3 above for vasculars)
  - 1.9.1 mycorrhizal
  - 1.9.2 saprophytic
  - 1.9.3 parasitic
  - 1.9.4 decomposer
- 1.10 moss feeder (invertebrates)

2 **Herbivory**
- 2.1 ungulate herbivory (may influence rate or trajectory of vegetation succession and presence of plant species)
  - 2.1.1 herbivory on tree or shrub species (browsers)
  - 2.1.2 herbivory on grasses or forbs (grazers)
- 2.2 insect herbivory (may influence rate or trajectory of vegetation succession or presence of plant species)
  - 2.2.1 defoliators
  - 2.2.2 bark beetles
  - 2.2.3 tree bole feeders

3 **Nutrient cycling relations (see category 6, below, for nutrient cycling relationships in soil)**
- 3.1 aids in physical transfer of substances for nutrient cycling (Carbon, Nitrogen, Phosphorus, other)
- 3.2 nitrogen relations
  - 3.2.1 N-fixer
  - 3.2.2 N-immobilizer
  - 3.2.3 source for N mineralization
- 3.3 carbon relations
  - 3.3.1 sequestration of atmospheric carbon

4 **Interspecies relationships**
- 4.1 insect control
- 4.2 ungulate or other vertebrate population control
- 4.3 pollination vector
- 4.4 transportation of seed, spores, plant or animal disseminules
  - 4.4.1 disperses fungi
  - 4.4.2 disperses lichens
  - 4.4.3 disperses bryophytes, including mosses
  - 4.4.4 disperses insects
  - 4.4.5 disperses seeds/fruits
  - 4.4.6 disperses plants
- 4.5 commensal or mutualist with other species
- 4.6 provides substrates or cover for animals
  - 4.6.1 nesting or breeding substrate (for example, nesting material)
  - 4.6.2 thermal, hiding cover, loafing or den site
  - 4.6.3 provides microhabitat (as for invertebrates)
    - 4.6.3.1 aquatic or riparian environments
    - 4.6.3.2 terrestrial environments
    - 4.6.3.3 canopy environments
    - 4.6.3.4 tree bole environments
  - 4.6.4 creates "sap wells" in trees
- 4.7 nest parasite
  - 4.7.1 cowbird
  - 4.7.2 host for nest parasitism
- 4.8 primary cavity excavator in snags or live trees
- 4.9 primary burrow excavator (fossorial)
  - 4.9.1 creates large burrows (rabbit, badger size)
  - 4.9.2 creates small burrows (smaller than rabbit size)
- 4.10 competitor
- 4.11 uses burrows dug by other species
- 4.12 secondary cavity nester
- 4.13 parasite (invertebrates)

5 **Disease, pathogen, and parasite relations**
- 5.1 carrier, transmitter, or reservoir of vertebrate diseases (including rabies)
- 5.2 acts as pathogen or disease
- 5.3 parasite carrier or transmitter
- 5.4 carrier, transmitter, or reservoir of plant diseases (invertebrates)
- 5.5 activity increases host susceptibility to plant diseases (invertebrates)

6 **Soil relations**
- 6.1 physically affects (improves) soil structure, aeration (typically by digging)
- 6.2 aids general turnover of soil nutrients and layers
- 6.3 aids N retention or uptake in soil
- 6.4 aids soil stabilization
- 6.5 aids rock weathering
- 6.6 detoxifies xenobiotics (invertebrates)
- 6.7 metal accumulator (sequesters heavy metals)
- 6.8 soil (invertebrate) organisms which influence rate or trajectory of vegetation succession and presence of plant species

7 **Wood relations**
- 7.1 physically breaks down wood
  - 7.1.1 large logs
  - 7.1.2 smaller wood pieces
- 7.2 chemically breaks down wood

8 **Water relationships**
- 8.1 impounds water (for example, beavers)
- 8.2 bioindicator of water quality
- 8.3 hydrologic buffer
- 8.4 improves water quality
- 8.5 contributes to short-term increase in stream flow (invertebrates)

9 **Weather, climate, insolation relations**
- 9.1 affects albedo (as of soil, rock, or soil)

10 **Vegetation structure and composition relations**
- 10.1 creates canopy gap openings (tree death) (invertebrates)
- 10.2 creates standing dead trees (snags) (invertebrates)

APPENDIX 5H

Locally endemic (LE) or regionally endemic (RE) vertebrates of the Basin.

Class[1]	Scientific name	Common name	Endemism
A	*Ambystoma gracile*	Northwestern salamander	RE
A	*Dicamptodon aterrimus*	Idaho giant salamander	LE
A	*Dicamptodon copei*	Cope's giant salamander	RE
A	*Plethodon dunni*	Dunn's salamander	RE
A	*Plethodon idahoensis*	Coeur d'alene salamander	RE
A	*Plethodon larselli*	Larch mountain salamander	LE
A	*Rana aurora*	Red-legged frog	RE
A	*Rana cascadae*	Cascades frog	RE
A	*Rhyacotriton cascadae*	Cascade torrent salamander	RE
B	*Centrocercus urophasianus*	Sage grouse	RE

Quigley, Thomas M.; Arbelbide, Sylvia J., tech. eds. 1997. An assessment of ecosystem components in the interior Columbia basin and portions of the Klamath and Great Basins. Gen. Tech. Rep. PNW-GTR-405. Portland, OR: U.S. Department of Agriculture, Forest Service, Pacific Northwest Research Station. 4 vol. (Quigley, Thomas M., tech. ed.; The Interior Columbia Basin Ecosystem Management Project: Scientific Assessment).

This paper provides detailed information about current conditions and trends for the biophysical and social systems within the basin. Social and economic conditions within the assessment area differ considerably depending to a great extent on population, diversity of employment opportunities, and changing demographics. This information can be used by land managers to develop broad management goals and priorities and provides the context for decisions specific to smaller geographic areas.

Keywords: Columbia basin, biophysical systems, social systems, ecosystem.

The **Forest Service** of the U.S. Department of Agriculture is dedicated to the principle of multiple use management of the Nation's forest resources for sustained yields of wood, water, forage, wildlife, and recreation. Through forestry research, cooperation with the States and private forest owners, and management of the National Forests and National Grasslands, it strives—as directed by Congress—to provide increasingly greater service to a growing Nation.

The United States Department of Agriculture (USDA) prohibits discrimination in its programs on the basis of race, color, national origin, sex, religion, age, disability, political beliefs, and marital or familial status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means of communication of program information (Braille, large print, audiotape, etc.) should contact the USDA's TARGET Center at (202) 720-2600 (voice and TDD).

To file a complaint, write the Secretary of Agriculture, U.S. Department of Agriculture, Washington, DC 20250, or call (800) 245-6340 (voice), or (202) 720-1127 (TDD). USDA is an equal employment opportunity employer.

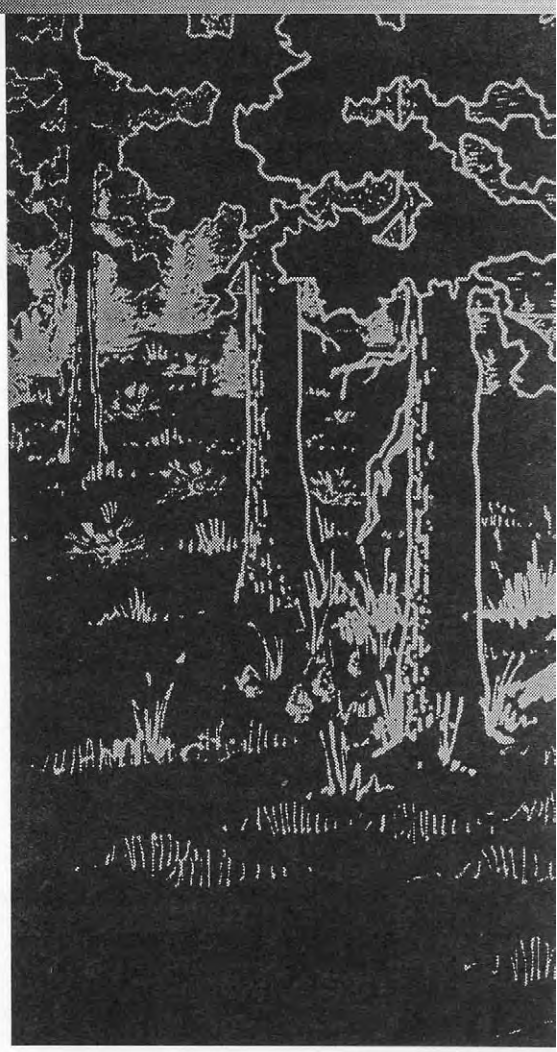
Abstract

Quigley, Thomas M.; Arbelbide, Sylvia J., tech. eds. 1997. An assessment of ecosystem components in the interior Columbia basin and portions of the Klamath and Great Basins: volume 4. Gen. Tech. Rep. PNW-GTR-405. Portland, OR: U.S. Department of Agriculture, Forest Service, Pacific Northwest Research Station. 4 vol. (Quigley, Thomas M., tech. ed.; The Interior Columbia Basin Ecosystem Management Project: Scientific Assessment).

The *Assessment of Ecosystem Components in the Interior Columbia Basin and Portions of the Klamath and Great Basins* provides detailed information about current conditions and trends for the biophysical and social systems within the Basin. This information can be used by land managers to develop broad land management goals and priorities and provides the context for decisions specific to smaller geographic areas. The Assessment area covers about 8 percent of the U.S. land area, 24 percent of the Nation's National Forest System lands, 10 percent of the Nation's BLM-administered lands, and contains about 1.2 percent of the Nation's population. This results in a population density that is less than one-sixth of the U.S. average. The area has experienced recent, rapid population growth and generally has a robust, diverse economy. As compared to historic conditions, the terrestrial, aquatic, forest, and rangeland systems have undergone dramatic changes. Forested landscapes are more susceptible to fire, insect, and disease than under historic conditions. Rangelands are highly susceptible to noxious weed invasion. The disturbance regimes that operate on forest and rangeland have changed substantially, with lethal fires dominating many areas where non-lethal fires were the norm historically. Terrestrial habitats that have experienced the greatest decline include the native grassland, native shrubland, and old forest structures. There are areas within the Assessment area that have higher diversity than others. Aquatic systems are now more fragmented and isolated than historically and the introduction of non-native fish species has complicated current status of native fishes. Core habitat and population centers do remain as building blocks for restoration. Social and economic conditions within the Assessment area vary considerably, depending to a great extent on population, diversity of employment opportunities, and changing demographics. Those counties with the higher population densities and greater diversity of employment opportunities are generally more resilient to economic downturns. This Assessment provides a rich information base, including over 170 mapped themes with associated models and databases, from which future decisions can benefit.



Keywords: Columbia basin, biophysical systems, social systems, ecosystem.

INTRODUCTION

The Charter of the Interior Columbia Basin Ecosystem Management Project (ICBEMP) charged the Science Integration Team to identify, among other issues, the economic outcomes associated with current Forest Service (FS) and Bureau of Land Management (BLM) activities in the assessment area. We identified three dominant economic themes having to do with (1) regional economies, (2) economic efficiency, and (3) equity. The importance of management of FS and BLM lands to regional economic activity is examined under the first theme. The theme of economic efficiency examines whether the resources associated with the Federal lands are being administered to provide society with good value. The theme of equity assesses how the benefits and costs provided by these Federal lands are being distributed throughout the population. Society is the judge of the fairness of the distribution, and it expresses its preferences through elected officials, legislation, and the judiciary.

The study area for the Interior Columbia Basin Ecosystem Management Project consists of the Columbia River basin east of the crest of the Cascades, and those portions of the Klamath and Great basins within Oregon (hereafter called the Basin). As such, it stretches through much of Oregon and Washington to the continental divide in western Montana and northwestern Wyoming, taking in nearly all of Idaho and small portions of Nevada and Utah. All or part of 100 counties lie within the Basin. The BLM and FS administer 53 percent of this land area. Private owners hold 38 percent of the area, state governments and other federal agencies manage 5 percent of the area, and tribal lands account for 4 percent of the area.

We begin this Economic Assessment with an "Overview" that characterizes the people and economies of the Basin. We describe the current situation and the trends and events that led up to it. We discuss how the economy in the Basin works, what it responds to, how sensitive it is to national business cycles, and what factors are driving economic growth. The FS and BLM administered lands that provide society with many benefits, few of which are pure private market goods. Because of this, a complete discussion of economics must go beyond prices and quantities. Many of the benefits provided by these lands have no prices and their quantities are not routinely measured. Laws and regulations reveal the importance society places on these benefits and shape the manner in which they are produced and used. The legal and political backdrop helps us understand society's preferences in allocating its scarce public resources.

A "Resource Characterization" section examines economic issues related to particular resources managed by the FS and BLM: fish, minerals, range, recreation, special forest and range products, timber, and water. For each resource in this section, we describe the current condition of the resource, the trends affecting resource demand and supply that led to the current condition, and what

the future of the resource may be. We discuss the importance of Basin FS- and BLM-administered lands, compared with lands outside the Basin or other ownerships in the Basin, in providing the resource, how much economic activity exists because of this resource, and how economic behavioral patterns relate to the resource. We also discuss values associated with each resource; we use the term "value" to mean relative importance, and express it in dollar terms. Because, for many reasons, market prices may not fully capture relative importance, "value" does not necessarily reflect money that changes hands.

Our "Economic Policy Questions" section provides a picture of (1) how important FS and BLM management activities are to community stability in the Basin, (2) how important FS and BLM management activities are to the development of regional economies in the Basin, (3) how future FS and BLM management may influence the ecosystem value provided society by these lands, and (4) an economic discussion of sustainability. The Economic Staff created the "Economic Policy Questions" section by weaving together information from earlier sections, conducting literature searches, and using computer modeling techniques.

In the "Economics of Ecosystem Management" subsection we explore the economic efficiency of alternative scenarios for management of FS and BLM lands in the Basin. We combine projections of resource supply and demand to examine the value of the "outputs" produced by different management regimes. We use "outputs" quite broadly to refer to the whole array of ecosystem goods, functions, and conditions people want from public lands. "Ecosystem goods" are specific components of ecosystems—minerals, timber, forage, mushrooms, salmon, or grizzly bears. "Ecosystem functions" are processes such as carbon storage or sediment filtration. "Ecosystem conditions" are systemic or integrated states such as "old-growth" forests, roadless areas, scenic integrity, or healthy ecosystems. "Value" refers to the strength of preference for or relative worth of an ecosystem output. We try to include most sources of value whether or not the outputs are traded in markets, and whether or not the people holding the values live in the Basin (Field 1994). By combining all this information, we attempt to display complementary outputs and tradeoffs associated with different management regimes; we examine how different public land management directions will affect the societal value of ecosystem goods, functions, and conditions produced by FS and BLM lands in the Basin.

Temporal Scales

Being explicit about temporal scales is critical to an economic assessment. Time must be treated explicitly because economic phenomena exist only at a point in time. A price, for example, is set by the instantaneous intersection of supply and demand; it will shift through time in response to changes in the underlying determinants of one or both. Time is similarly important in understanding behavior pertaining to non-market goods, particularly ones for which societal preferences have changed significantly.

We document historical resource use and economic activity as far back as Basin-wide data of consistent quality are available, often only to 1969. Our discussion of the future is based on 50-year projections gathered from the Resource Planning Act Timber Assessment (Haynes and others 1995), the CRBSUM computer model,[1] the Bureau of Economic Analysis (U.S. Department of Commerce 1992), and U.S. Bureau of the Census (Day 1993, Campbell 1994). We display projected trends in activity of various economic sectors to show how the economy is expected to evolve over the next half century. We also display trends in net economic values over time to reveal allocation of benefits between current and future generations; this is in lieu of the more traditional present net value (PNV) analysis. These projections allow greater precision in evaluating the relative importance of any changes, rather than generalizing to "the economy improves" or "jobs shift."

[1] CRBSUM is the spatially explicit dynamic model developed by the Landscape Ecology staff of the Interior Columbia Basin Ecosystem Management Project.

Spatial Scales

A principle of ecosystem management is to set and understand context one level higher than the primary scale of interest and to examine and understand processes one level lower than the primary level. Our primary spatial scale of interest is the Basin. When using county-level data, we have defined the region as the 100 counties into which any part of the Basin falls, although for some of these counties the land area and economic activity that occur within the Basin are minor. To set context, we discuss market and non-market economic phenomena at the national level. To understand processes, we have defined two sets of subregions within the Basin: one set is used to examine regional economies, the other to examine the societal value of what might be supplied by BLM and FS lands in various ecosystems.

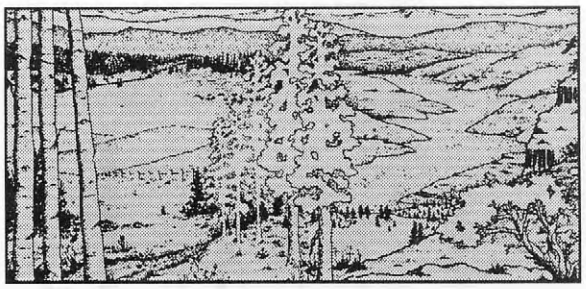
When discussing the regional economy, we use nine economic regions, shown in map 6.1, modified from a recent publication by the Bureau of Economic Analysis (BEA) (U.S. Government 1995). The BEA defined functional economic units by identifying economic nodes and the surrounding counties economically related to them. Work commuting patterns are the primary factor used to determine economic regions. The goal is to include, as far as possible, both the place-of-work and place-of-residence of the labor force. Some parts of the Basin function as part of economic units that include areas outside the ecological boundary; Redmond-Bend, Oregon, for example, is not a stand-alone economic node, but is associated with the larger economic unit related to Portland west of the Cascades. For this analysis, we modified BEA regions to include only those counties in which the Basin falls, but the point remains that economic regions and ecosystems are often not coincident. Further, we consider the BEA regions to be the smallest economic unit relevant to conducting an economic assessment of an area the size of the Basin. They do not, however, operate independently; rather, they function as part of larger regional and global economies.

When exploring the question of what ecosystem goods, functions, and conditions the FS and BLM lands in the Basin provide society, we are really concerned about supply, or rates at which outputs are produced. Hence in the "Economics of Ecosystem Management" subsection we use the 13 Ecological Reporting Units (ERUs) developed by the Aquatic, Landscape Ecology, and Terrestrial staff areas (map 6.2). (The decision by the ecologists to use groupings of subbasins instead of or in addition to ERUs occurred too late for us to redo our analyses.) These ERUs are regions in which lands have similar capacities to produce the various ecosystem goods, functions, and conditions desired by society. Different ecosystems have inherent differences in their ability to supply society with certain outputs. For example, the Central Idaho Mountains ERU is a better place to put ski resorts than the Northern Great Basin; the Blue Mountains ERU is a better place to grow trees than the Upper Snake ERU.

One observation about spatial scales is that every BEA area includes parts of several ecological regions. All trade centers in the Basin are located at the boundaries between ecoregions (with the exception of the Tri-Cities which is an artifact of Federal projects). This suggests the hypothesis—untested here—that spheres of economic activity will tend to exist where they can draw from several different ecological regions; that the diversity of ecosystem outputs provided by having access to several ecoregions provides economic advantages. This interweaving of economic and ecologic areas reinforces the notion that regions should be defined differently depending on whether one is answering a question about economic activity or about what Federal lands can supply to best meet society's needs.

Map 6.1— Bureau of Economic Analysis economic areas of the Basin.

Map 6.2— Ecological Reporting Units of the Basin.



General Findings

Regarding the role of FS and BLM management in maintaining community stability, we find little evidence that agency management succeeds in maintaining community stability through timber harvest levels. The isolation and lack of economic diversity of certain communities make them sensitive to changes in interest rates, labor productivity, consumer preferences, and national business cycles—all factors over which the FS and BLM have little influence. The Basin contains 539 census-recognized places, of which 66 were defined by the FS in 1987 as timber dependent. Today only 29 of these exhibit characteristics suggesting heightened sensitivity to Federal timber sales (see section on "Community Stability and Timber Dependency").

For the entire Basin, we find that current FS and BLM activities have little impact on its economy. It has a large, diverse economy of 1.5 million jobs. The past two decades have seen rapid population growth and the evolution from a mature, resource-based economy to a diverse economy oriented toward the technology, transportation, and service sectors. We expect the economic growth in the Basin to continue, especially in the finance, insurance, real estate, transportation, agricultural services and service sectors. The manufacturing, agriculture, and government sectors are expected to decline over the next 50 years (see "Economic Growth" section).

We had data which allowed us to include range, recreation, timber, and the existence of unroaded areas in our economic efficiency analysis. Range provides 0.4 percent of the net benefit of FS and BLM lands in the Basin, recreation provides 41.2 percent, timber provides 11.5 percent, and the existence of unroaded areas provides 46.9 percent. Changes in society, particularly population growth and aging, will shift the relative importance of these activities over time. We expect that by the year 2045, recreation will be providing 52.9 percent of the value of benefits to society. Motor viewing (pleasure driving) will be the highest value activity in the Basin, followed by day use and trail use. The relative importance of timber will have fallen to 5.4 percent (see "Economics of Ecosystem Management" section). Roads and access to riparian areas are an aspect of recreation supply common to what will be the most highly valued activities on FS and BLM lands over the next 50 years.

Considerable revenues could be raised by charging recreation fees. If the formula for calculating payments to counties were revised to reflect the recreation value of these lands, their revenues could double or triple.

OVERVIEW

This section describes the human and economic context of BLM and FS lands within the Basin. It describes federal, private, and tribal landownership patterns within the Basin. It also characterizes the people who live in the Basin and their economies. The evolution of economic and demographic characteristics in the Basin are described together since the two are inextricably linked.

Demographic and Economic Trends[2]

Current Picture

The land—The FS and BLM manage slightly more than half (53%) of the lands in the Basin; the second largest category is private ownership (38%) (fig. 6.1). Minor portions are owned by State and other Federal agencies (5%), and the tribes (4%). The highest percentage of FS and BLM landownership and lowest percentages of private landownership are found in the Central Idaho Mountains Ecological Reporting Unit (ERU) (81% and 14% respectively) and the Northern Great Basin ERU (73% and 21% respectively). At the other extreme the Columbia Plateau ERU is predominantly private landownership (12% FS or BLM and 76% private). The Snake Headwaters ERU has the highest percentage of National Park and other wilderness (11%). Significant percentages of tribal lands are found in the Northern Glaciated Mountains (17%), Northern Cascades (12%), and Southern Cascades (9%). All other ERUs more closely resemble the overall Basin ownership patterns.

The percent of the land base in different ownerships helps to identify ERUs whose ecosystem integrity is directly affected by BLM and FS land management policies. The amount of private land in each ERU is important because the amount of timber harvesting and cattle grazing on FS- and BLM-administered land affects the amount of production which occurs on private land. The two are inversely related; that is, through market signals decreases in grazing or harvesting from FS- and BLM-administered lands encourage increased production from private lands— in either the short or long term. Nonmarket outputs (outputs not traded in markets) desired by society are often best produced from public lands because public management can internalize and directly control for their production levels. Without government regulations and incentives, privately owned lands may not produce nonmarket outputs.

Among the forested ERUs, the FS and the BLM have greatest potential influence on the ecosystem integrity of the Central Idaho Mountains where they manage 81 percent of the land base (see fig. 6.1). The FS and BLM have the least potential influence in the Northern Glaciated Mountains (FS and BLM manage 39%); and private management has its greatest influence in the Upper

[2] This section was written by Amy L. Horne, based on the background report prepared by McGinnis and Christensen [1996].

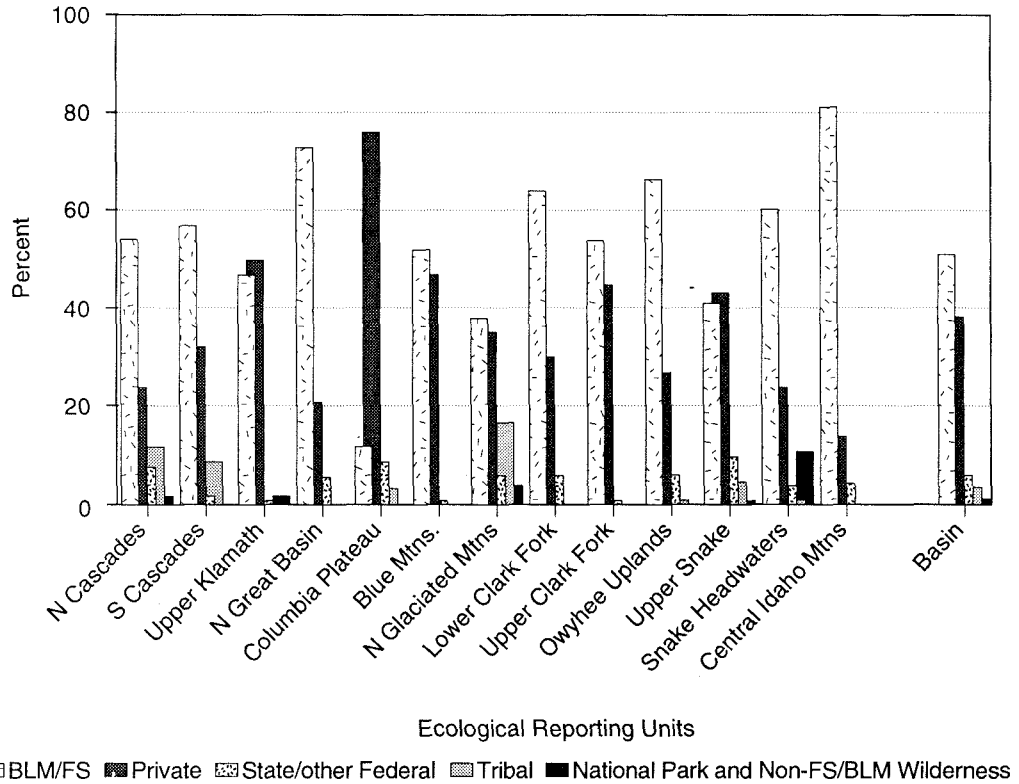


Figure 6.1— Land ownership patterns in the Basin and by Ecological Reporting Unit; categories are BLM and FS, National Park and other wilderness (not FS or BLM), other Federal and State, Tribal, and Private, 1995.

Klamath (50% private). Among the nonforested ERUs, the FS and BLM have the greatest potential influence in the Northern Great Basin (73% FS and BLM, 21% private), and the least in the Columbia Plateau (12% FS and BLM, 76% private).

The people—In a nation that has become largely urban, the Basin is strikingly rural. It accounted for 1.2 percent of the population of the United States in 1990. Over 77 percent of the U.S. population lives in urban areas; in the 13 western states[3] the percentage is even higher (84.6%) (Krannich and others 1994). By contrast, only 31 percent of the population in the Basin lives in urban areas, none of which contains more than one million people; only six of the 100 counties are considered metropolitan (McGinnis and Christensen 1996).[4] Sixty counties are in the most rural category defined by the Census Bureau: non-metropolitan and neither adjacent to a metropolitan county nor containing a community of at least 10,000 people; these 60 counties account for less than 25 percent of the Basin population.

Population density on non-public lands within the Basin is less than one-third of the U.S. average: on average, 20 people dwell in one square mile within

[3] The West Census region includes Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming (Campbell 1994).

[4] The Census Bureau defines a metropolitan county as one in a metropolitan statistical area (MSA). An MSA has a population of at least 100,000 and includes a large population center of at least 50,000 and adjacent communities that are economically and socially integrated with it. The metropolitan counties in the Basin are: Benton, Franklin, Spokane, and Yakima Counties (Washington), and Ada and Canyon Counties (Idaho) (McGinnis and Christensen 1996).

the Basin as opposed to 70 people per square mile for the Nation. Including Federal lands drops population density to 11 people per square mile. Sixty-two percent of the population lives within the Basin in communities of less than 10,000 people, in unincorporated places, or in open countryside—much higher than the 43 percent average for the United States (fig. 6.2). These averaged population densities mask tremendous variation across the Basin, from less than one person per one-square-mile in Harney County, Oregon, to as high as 338 people per one-square-mile in Ada County, Idaho.

People living in the Basin are similar to other people in the United States in age structure, educational attainment, occupational distribution, and sources of income, although variation exists across the Basin. The Basin has a slightly higher percentage of people under the age of 18 than the U.S. average (28.9 versus 25.6 %) and a lower percentage of people in the prime wage-earning years of 25 to 49 (36.0 versus 38.0%). Forty-eight percent of those people living in the Basin have achieved at least some level of higher education compared with 45 percent in the United States as a whole, suggesting it has a high quality workforce. The racial and ethnic composition of the Basin, however, is quite different from the rest of the country. Generally, the Basin has a higher percentage of Caucasians than the United States (91.7 versus 80.3 %); it also has a greater proportion of Native Americans (2.4 versus 0.8 %) and a smaller proportion of African-Americans (0.6 versus 12.1%), Hispanics (6.7 versus 9.0 %), and Asians (1.1 versus 2.9 %).

The economy—Overall, the economies of the four states making up the bulk of the Basin (Idaho, Montana, Oregon, and Washington) are doing well. In 1990 their economies comprised 3.6 percent of the national economy. Washington State's economy was larger than the sum of the other three (U.S. Department of Commerce

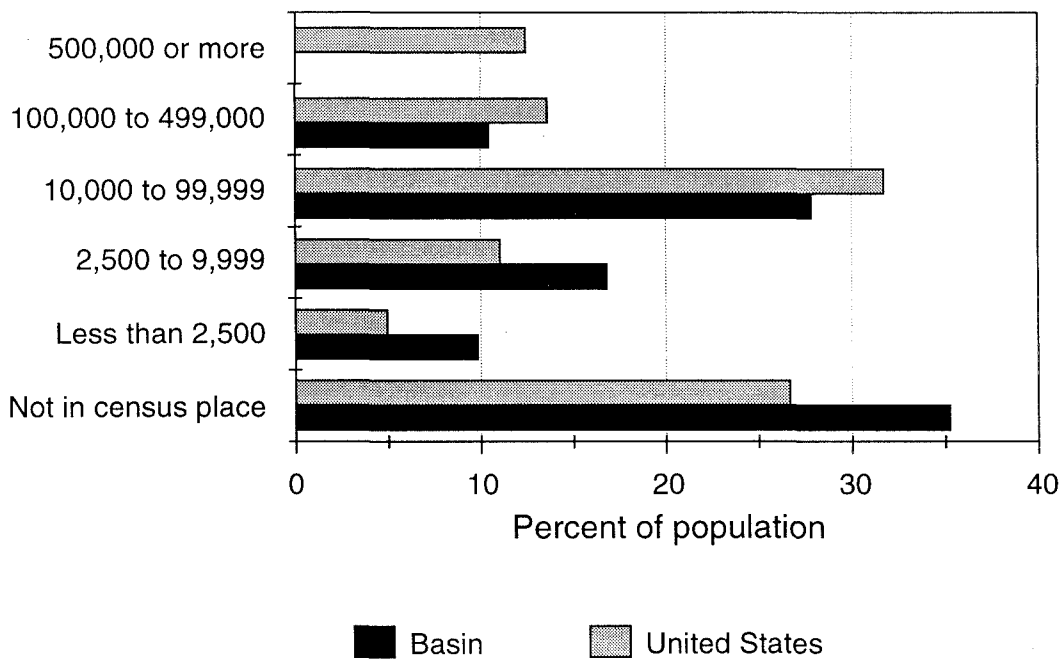

Figure 6.2— Population distribution among places of different sizes; United States and the Basin, 1990.

1993). Washington is the only one of the four states with higher per capita income than the U.S. average, but in all four states per capita income is growing faster than the U.S. rate (table 6.1). Similarly, "earnings per job" are increasing in Montana, Oregon, and Washington faster than in the United States; only Idaho has a smaller percent change. Poverty rate and percent change is lower than the U.S. average in Idaho, Oregon, and Washington, but not Montana. Unemployment rates in Idaho and Montana are lower than the U.S. average and decreasing at a faster rate. In Oregon and Washington the reverse is true: unemployment rates are higher than the national average and falling at a slower rate.

The six metropolitan counties in the Basin have been the center of its economic growth, with higher rates of growth in total employment, total personal income, and non-farm labor income, and a greater ability to weather national recessions than other counties. They tend to have lower per capita incomes than their counterparts throughout the United States; this gap has been widening since 1980. Some economists believe this indicates that amenities are attracting surplus labor, as has been found elsewhere (Treyz 1993, Power 1996); alternatively, these smaller metropolitan areas lack the highest paying jobs. Earnings per job in metropolitan areas of Idaho (primarily Boise) are increasing at a faster rate than the national average. Poverty rates in Washington's metropolitan counties are increasing at a faster rate, though the levels are still lower than the national numbers.

The non-metropolitan counties in the Basin have even better economic indicators than metropolitan counties. Per capita income is higher than the national average in all four states, although Montana's growth rate is lower than the national average. Earnings per job in non-metropolitan counties are higher than the national average everywhere except Montana.

Economic Strengths of the Basin

The Basin's economy is small relative to the United States; it accounted for only 1 percent of U.S. employment in 1995. We characterized the economic strengths of the Basin by identifying those economic activities within it that have a higher percentage of employment than the benchmark economy of the United States (Weimer and Hoyt 1948). Data showing the percentage employment in various economic sectors (see table 6.2) suggest that the traditional notion that manufacturing is the driving sector of the Northwest economy is too narrow (for example see Beuter 1995). Not surprisingly, economic strengths of the Basin include agriculture and agricultural services. Mining and manufacturing, are less important to the Basin's economy than to the Nation's. Basin-wide, including both public and private lands, timber and wood products [Standard Industrial Classification (SIC) 24] account for 2.6 percent of the jobs, cattle grazing accounts for 1.0 percent of the jobs, and mining accounts for 0.4 percent of the jobs (fig. 6.3). The percentage of jobs attributable to recreation is not shown here because the BEA does not define it as an industry. In the discussion of recreation below, we calculate that 14.6 percent of jobs in the Basin is attributable to recreation.

Note: Farm employment is calculated as the difference between total employment and covered employment. Because it is calculated as a difference it includes rounding errors.

[1]Redmond-Bend is the portion of the Portland-Salem BEA region that is inside the Basin.

[2]Sources for lumber and wood-products manufacturing (SIC 24) employment.

[3]1990 data (Beuter 1995).

[4]Financial, insurance, and real estate industries.

A more complex story emerges by looking at individual BEA regions (see map 6.1) within the Basin. Agriculture is an economic strength in every region except the Butte BEA region. Mining in the Butte BEA region is double the national average, and it is important in the Idaho Falls BEA region as well. Manufacturing is a strong activity only in the Pendleton and Redmond-Bend BEA regions, and forest products and food processing are important components of both. The importance of trade in each BEA region (except the Pendleton region) mirrors the Nation. The same can be said about the service sector except that there is more variability around the Basin. In the Boise BEA region, finance, insurance, and real estate (FIRE) are important activities. In several BEA regions construction and transportation are strong parts of the economy. The percentage of jobs supported by recreation is highest in the Idaho Falls (30%), Missoula (31%), and Redmond-Bend (25%) BEA regions (see the "Recreation" section for more information).

Historical Perspective

Populations in the sparsely settled lands east of the Cascade Range grew rapidly between 1890 and 1920, then stabilized or declined due to restructuring of agriculture and shifts in economic opportunities (Robbins and Wolf 1994). Between 1960 and 1990, population in the western quadrant of the United States had the fastest growth rate (88.2 % versus 39 % for the Nation), increasing its percent of the U.S. population from 15.6 to 21.2 percent. Much of the growth in the western states during this period occurred outside the Basin; however, the population of the Basin still grew faster than the population of the United States. Since the 1960s the population growth in the Basin has been highest in those counties adjacent to protected, usually Federal, lands (Rudzitis 1995). Some economists conclude from this that areas with high amenity values attract new businesses and skilled labor (Power 1996).

Business cycles in the Basin generally mirror those of the total U.S. economy (see table 6.3), with corresponding periods and similar rates of expansion and decline. In certain periods, the effects of national business cycles on demographics and economics within the Basin have shown departures from the norm. The Basin's economy fared better than that of the United States during the generally prosperous decade of the 1970s. Population growth out-paced even that of the 13 western states and, on average, census locations grew rapidly regardless of size. The Basin's prosperity was associated with a national "rural renaissance" that ran counter to the general trend of increasing urbanization. This renaissance was driven by decentralization of manufacturing and services for health and education, reduction in the rate of people leaving agriculture, increased residential sprawl of metropolitan commuters, modernization of rural communities and roads, and increased preference for small town life (McGinnis and Christensen 1996).

During the 1970s total employment in the Basin grew faster than for the United States and showed little effect from the national 1974-1975 recession. Non-farm labor income, an indication of the response of a regional economy to national business cycles, grew faster than the U.S. economy during expansions and did not slow down as much as the U.S. economy during the recession. Although per capita income grew more slowly than the national rate, this effect was counterbalanced by growth in employment. Consequently, the buying power of the Basin's economy increased relative to that of the United States: total personal income (the product of employment and per capita income) grew by 70.9 percent versus 64.4 percent for the United States.

The slower than average per capita income growth in the Basin during the 1970s can be interpreted several ways: there may have been structural shifts in the Basin's economy leading to a smaller proportion of high-paying jobs, or the Basin may have had an abundant labor supply that enabled businesses to attract sufficient labor without raising

Table 6.3—Population, gross national product, and income figures for the United States, 1929-1994 and projections to 2040.

wages. Some economists argue that the latter can happen when a region offers a high quality of life such that people are willing to work for less in exchange for the amenities of living there (Whitelaw and Niemi 1994). The demographic effects of amenity-driven migrations on regional growth have been modeled for at least 40 years.[5] In the Basin, public lands are a dominant provider of amenities; recent survey evidence suggests that these amenities do provide an incentive for economic growth.[6]

In the 1980s the Basin's economy had a different response to national business cycles. The 1980-1982 recession disproportionately affected commodity markets such as agriculture and timber, putting the Basin's economy in a deep recession from which it recovered at a rate slower than that of the United States. All the demographic and economic indicators—total employment, per capita income, total personal income—grew more slowly than for the United States. Population in the Basin still grew by 6 percent, but included a 9 percent rate of natural increase (births minus deaths) offset by a 3 percent rate of out-migration. The age structure of the Basin changed markedly with a 27.6 percent increase in the 65-and-older age group, primarily due to the aging of the resident population rather than to migration.

The different ways in which population can change, natural increase, in-migration, or out-migration, have important consequences for regional economies. Natural increase has long-term, slowly felt impacts since expenditures associated with household formation are delayed for 20 years. Migration has an immediate effect on the tax base and the demand for goods and services associated with household formation. Thus shifts in net migration, in or out of the Basin, have a greater impact on rates of economic growth than natural increase.

A shift toward net in-migration occurred in the late 1980s, and population growth continues to be an economic and demographic hallmark of the region today (Sommers and others 1995). Between 1990 and 1992, States in the study area were some of the fastest growing in the Nation: Nevada (11.1%), Idaho (5.9%), Washington (5.7%), and Oregon (4.6%) all grew well above the U.S. rate of 2.6 percent. Since 1990, the population in the Basin has been growing faster than the national average for all degrees of urbanization; small metropolitan counties grew the fastest at 6.3 percent, non-metropolitan counties adjacent to metropolitan ones had the next fastest rates of growth at 5.8 percent. Recent evidence indicates that renewed growth in non-metropolitan areas may be part of a new national trend. This may explain why the U.S. recession of 1990-1991 had little impact on the Basin; during this period, nonfarm labor income in the Basin grew faster than it had during the national expansion between 1983 and 1989.

Associated with recent population growth in Idaho, Montana, Nevada, Oregon, and Washington is the evolution from "a mature resource-based economy to one that is becoming a major player in advanced technology, retail, and transportation services" (Sommers and others 1995). The information age has restructured the economies of these states leading to more rapid expansion in non-manufacturing than manufacturing sectors. Construction and real estate businesses, because they are associated with the population growth, have been robust. The gaming sector, casinos and the like, has also shown explosive growth. The producer-services sector, which includes finance, engineering, management, law, advertising, computer programming, building maintenance, and guard services, has also grown rapidly.

In contrast, the forest products sector in the Northwest economy (see table 6.2), continues to decline. Market watchers expect more changes and downsizing to be involved in reaching new levels of equilibrium harvest (Sommers and others 1995). On the other hand, some components of the forest-products sector have been growing rapidly, particularly manufactured housing, millwork production, and the paper sector.

Differences Among Non-metropolitan Counties

Because one of the policy questions relevant to the ICBEMP deals with economic growth in non-metropolitan counties, we wanted to learn whether there are any structural characteristics of counties which exhibit greater economic growth or resiliency. A typology of non-metropolitan counties developed by the Economic Research Service (ERS) (initially in 1979, and updated with three new categories in 1989) has six categories of economic specialization based on the derivation of income:[7] farming, manufacturing, mining, government,[8] services, and nonspecialized (counties that fell into no other group)(Cook and Mizer 1994). The typology also has five policy categories: retirement,[9] Federal land,[10] commuting,[11] transfers-dependent,[12] and persistent poverty.[13]

We added a sixth policy category—recreation counties[14] (Johnson and Beale 1995)—because in the Basin, over 80 percent of recreation value on public lands is derived from BLM- and FS-administered lands and their management has important implications for economic development.

One question concerns the likelihood that a county's economy will resemble its current structure in ten years. We wondered whether the likelihood of change could be correlated with the predominant economic activity: for example whether farming counties are more likely to evolve into something else than manufacturing counties. In the 1989 typology, about one-third of the counties in the Basin were classified in the same categories as in 1979, changes in one-third may be due to the new categories or changes in definition, and the remaining third experienced real changes in the composition of their economies (table 6.4) (McGinnis and Horne 1995). The farming category was the most common and most stable among Basin counties. The manufacturing and retirement categories lost the most counties in both percentage and absolute terms. The farming and the nonspecialized categories gained the largest number of counties. Of the 14 nonspecialized counties in the 1989 typology, five had been in a specialized economic group in 1979 but strengthening of other sectors diminished the importance of the formerly dominant sector (see McGinnis 1996).

Many county economies ceased to be dominated by manufacturing because of losses in wood products or minerals processing. For example, Gem, Idaho, Grant, and Harney Counties in Oregon, and Klickitat County, Washington changed from manufacturing- to farming-dominant, while Idaho and Nez Perce Counties in Idaho, Klamath County in Oregon, and Stevens County in

[7] Service activities contributed a weighted average of at least 50 percent of labor and proprietor income 1987-1989. Service activities include private, personal, and agricultural services, wholesale and retail trade, finance and insurance, transportation, and public utilities.

[8] Government includes federal, state, and local offices; military installations; public educational and health facilities; prisons; transit, housing, port, customs, airport and other special purpose authorities; public housing; and units that manage public resources (forests, rangeland, and parks).

[9] Retirement counties had 1970-1980 net in-migration rates of people aged 60 and over that were at least 15 percent of expected population for this age group in 1980.

[10] Federal counties had at least 33 percent of the land area in Federal ownership in 1977.

[11] At least 40 percent of workers commuted to jobs outside the county in 1990.

[12] At least 25 percent of total personal income was accounted for by federal, state, and local transfer payments 1987-1989.

[13] Persistent poverty counties had per capita personal income in the lowest quantile in 1950, 1959, 1969, and 1979.

[14] Recreation counties were defined using several income, employment, and noneconomic indicators--such as percent seasonal housing. They include places that specialize in recreation unrelated to outdoor activities, such as gaming.

Table 6.4—Typology of non-metropolitan counties in the Basin; change in number of counties within each economic or policy category between 1979 and 1989.

Economic or policy group	Number of counties 1979	Number of counties 1989	Number of counties in same category
Metro	5	6	5
Economic Groups			
Farming	31	35	29
Manufacturing	19	12	9
Mining	4	6	3
Government	11	10	7
Services	NA	17	NA
Nonspecialized-unclassified	6	14	3/9[1]
Policy Groups			
Retirement	16	7	5
Federal lands	65	64	61
Commuting	NA	5	NA
Transfers	NA	6	NA
Persistent poverty	0	1	0
Recreation	NA	18	NA

NA= "Not Applicable" since this group was not defined in the 1979 typology.
[1]Three of these counties were unclassified in 1979, but six others did not qualify for any economic group in 1979.

Washington became nonspecialized. Bonner County in Idaho and Jefferson County in Oregon came into the manufacturing group because of increases in wood products income. Note that the instability of the manufacturing county group was evident prior to the 1991 Judge Dwyer[15] decision (enjoining FS timber sales until a management plan for northern spotted owl habitat was developed) and was largely influenced by forces other than FS or BLM policy. The large drop in retirement counties appears related to the juxtaposition of high in-migration during the 1970s and slow population growth during the 1980s, making it difficult to meet the criteria of having retirement age in-migration be 15 percent of the expected retirement-age population. One retirement county became metropolitan (Canyon County, Idaho).

We examined trends in various economic indicators to see whether particular groups have shown consistent patterns (figs. 6.4 and 6.5). Of the economic groups, the services-dependent counties have consistently shown the highest rates of economic and population growth since 1970. This group includes counties with trade-center towns (Idaho Falls, Twin Falls, and Missoula), and growing recreation and tourism economies (Sun Valley, Kalispell, Jackson Hole, and Elko). Since the early 1980s this economic group has had the highest per capita income. Its employment and total personal income growth rebounded much faster after the early 1980s recession than the other economic groups. This was the only economic group having net in-migration between 1980 and 1990.

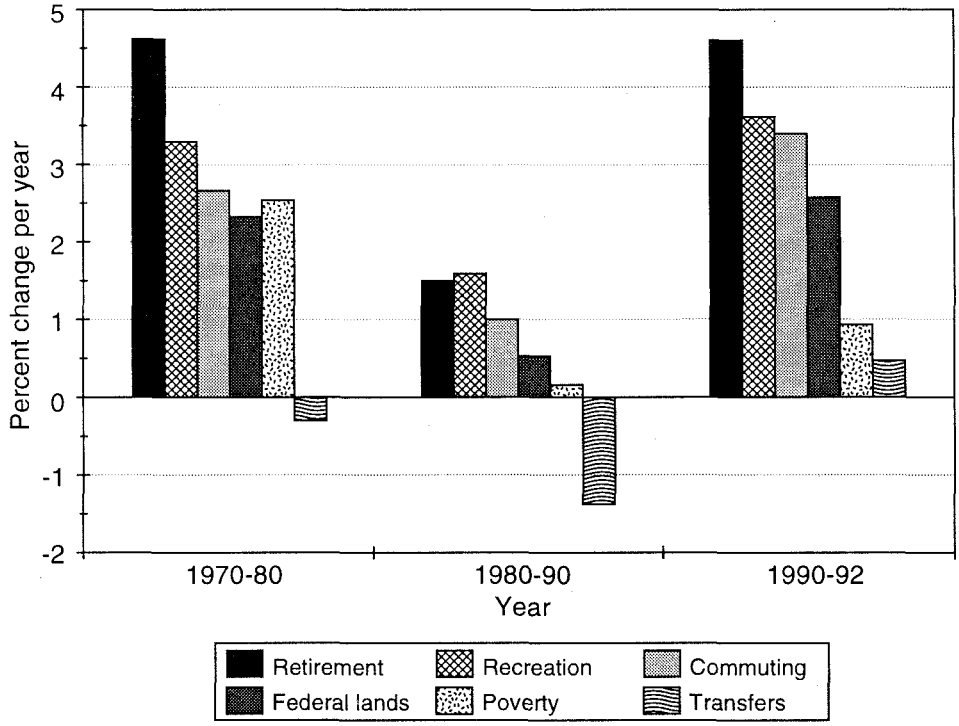

Figure 6.6— Rate of population change in the Basin counties within each category of policy typology, average annual percent change, 1970-1992.

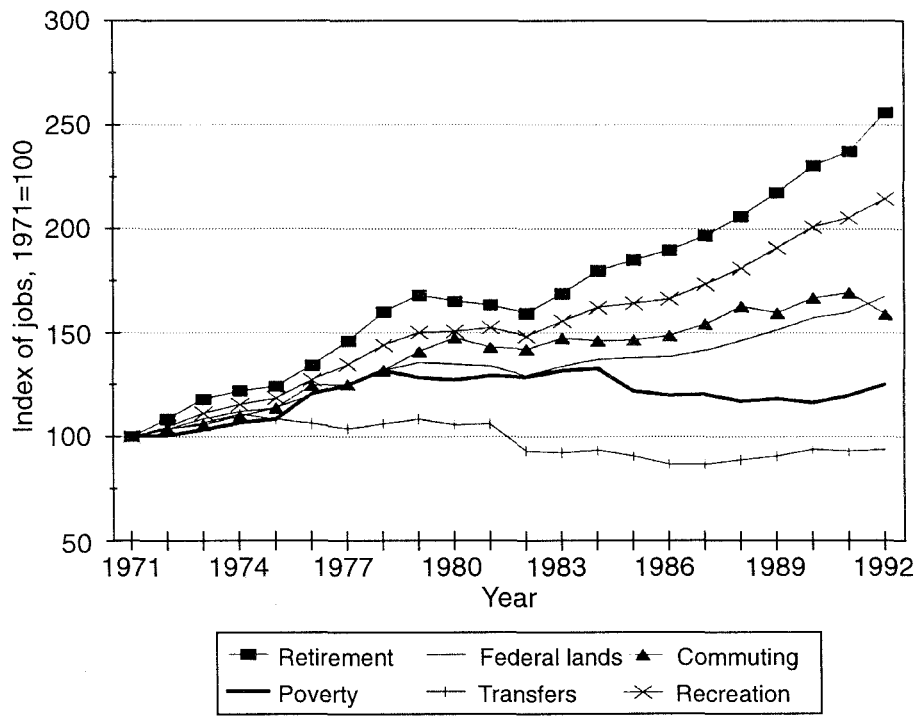

Figure 6.7— Annual change in employment in the Basin counties, within each category of policy typology, 1971-1992.

The mining counties have had the most volatile economies in the past 25 years. They fared well in the 1970s, but in the 1980s suffered population losses and very slow rates of job growth. The fluctuations in the mining sector were clearly evident as total personal income declined by 20 percent in the mid-1980s. Per capita income tends to be cyclical (though not in step with national business cycles), but the average salary is now the highest among the non-metropolitan groups in the Basin.

Farming counties posted lower growth rates than the Basin average during the 1970s and the 1980s and also exhibited greater volatility in per capita income than other non-metropolitan counties. The government, manufacturing, and nonspecialized counties tended to follow similar patterns of fast economic growth in the 1970s (though slower than the services, recreation, and retirement groups), very slow growth following the early 1980s recession, and renewed growth late in the decade.

The manufacturing group has had the lowest per capita income of the economic groups but the second highest salary per job. This seeming incongruity can be explained by differing labor force participation rates, age and family structures, and commuting patterns (McGinnis and Horne 1995). Most of the economic and policy groups show salary per job tracking the Basin average for non-metropolitan counties and following the trend of declining real average salaries since the mid-1970s. The government group is the exception with significantly lower average salary than the other groups since 1970.

Among the policy groups, recreation and retirement counties have shown consistently high rates of growth in population, total employment, and total personal income over the last 20 years (figs. 6.6 and 6.7). They were the only two groups showing substantial net in-migration in the 1980s. Between 1990 and 1992, retirement counties continued to have the highest rates of population growth among the non-metropolitan counties, followed closely by recreation and commuting counties.

The recreation counties have consistently had the highest per capita income of the policy groups. A comparison of recreation and manufacturing counties found this is in part because residents of recreation counties derive more income from non-salary sources such as investments and transfers than residents of manufacturing counties (fig. 6.8). This supports arguments by some economists that recreation counties attract people with high property income and wealthy retirees. But residents of recreation counties also have higher employment earnings per capita despite having lower average earnings per job (McGinnis and Horne 1995). This seeming contradiction stems in part from residents of recreation counties having fewer dependents per wage earner (which would increase per capita earnings) than those of manufacturing counties. It is also due to differences in how the two numbers are calculated; earnings per capita are calculated by county of residence, and earnings per job are calculated by county of employment—thus

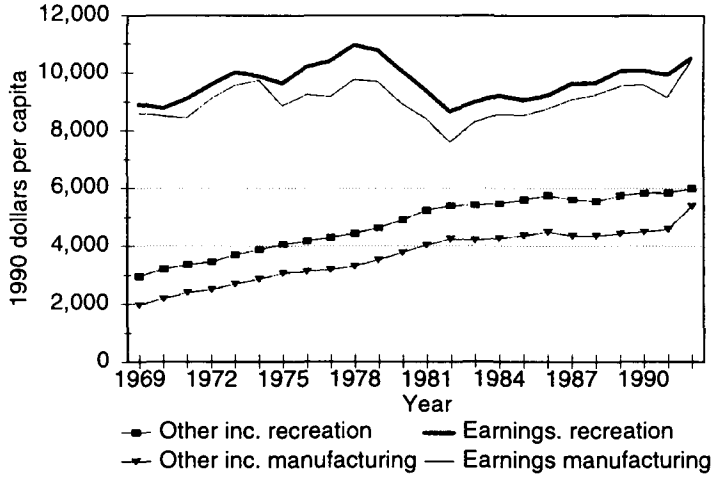

Figure 6.8— A comparison of per capita income in recreation and manufacturing counties within the Basin, divided into income from earnings and other (property and transfers).

people who commute between counties can skew the results. In both recreation and manufacturing counties the net effect of commuting is to remove income, but the impact per capita is greater in manufacturing counties.

In contrast to growth in the rest of the Basin, counties dependent on transfer payments experienced 20 years of sluggish growth and population losses. Three of the six transfers-dependent counties experienced closures of mines or smelters in the 1980s. These counties show the typical pattern of out-migration of working-age population following economic collapse and with it an increase in the importance of transfers among the remaining, primarily older, population.

Outlook

The U. S. population is expected to continue to grow, albeit at a declining rate, over the next 50 years (Marcin 1993). The population will become older, more affluent, more educated, and more racially and culturally diverse. The gross national product is expected to grow at an average rate of 2.7 percent over the next half century, and growth in per capita disposable income is expected to increase in line with general aging (see table 6.3). The economy is expected to evolve toward information-based technologies and service, and away from agriculture and forestry (Marcin 1993).

We expect the general economic growth of the past five decades in the Basin to continue. One implication of this is steady growth in per capita income and sustained in-migration in parts of the Basin. By the year 2040, the Basin population is expected to increase in size from between 407,000 (14%) and 3.6 million (108%).[16]

[16] The 407,000 figure represents the lowest projection available and was derived by distributing projections in national employment and earnings by industry down to states and counties based on historical growth rates (U.S. Department of Commerce 1992). The 3.6 million figure was derived from U.S. Census projections of rates of natural increase and migration patterns similar to recent trends (McCool and Haynes 1996).

Demographic trends are likely to have significant impacts on the Basin—primarily in changing its rural nature but also in what society will want from its public lands. Increased residential development adjacent to public lands will increase pressures to control fires and to modify some forest practices. The types of people attracted to the Basin may be more interested in ecological issues and passive-use values than traditional extractive industries. Retirees may increase the demand for bird-watching, walking, and picnicking. Improvements in transportation and telecommunication systems may attract population and business to the Basin's small metropolitan areas.

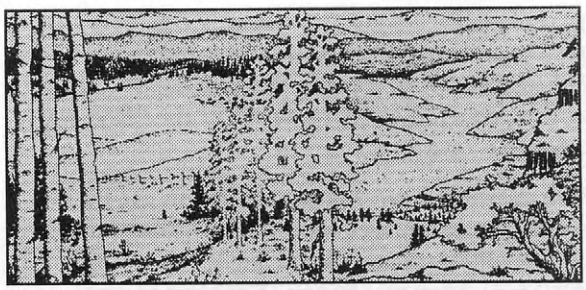
All these factors suggest increased stresses and conflict over land-use in the Basin. Residential developments tend to be located on private lands adjacent to public lands, often in riparian areas. These developments will detract from scenic vistas and could further impair functioning of riparian ecosystems. Allocation of water between agriculture, residential, and instream-use may become increasingly controversial.

By the year 2040 the BEA expects economic sectors in the Basin to exhibit differential growth rates but no change in rank. Using population projections by McCool and Haynes (1996) and BEA employment projections (U.S. Department of Commerce 1990, 1992), we found greatest growth in the service sector (including health, business, educational, and legal services) which is expected to increase by 456,000 jobs by the year 2040. The average wage rate in the service sector currently is $18,185 per year, placing it eighth out of 11 sectors. Other sectors in which employment is expected to grow are trade (314,000 new jobs); government (186,000 jobs, 75% of which will be at state and local levels); and manufacturing (148,000 jobs). The agricultural services sector, which includes farm operators and managers, nursery workers, tree planters, and inspectors of agricultural products, is expected to increase by

60,000 jobs by the year 2040. The average wage rate in this sector is the lowest of all sectors ($11,300 per year) and is expected to remain lowest in 2040. On a percentage basis, the fastest rate of job growth will be in the service sector, followed by agricultural services, trade, and FIRE (finance, insurance and real estate).

The BEA projections show declines in the percentage of jobs in the Basin in (in decreasing order) farming, government, and manufacturing sectors. The durable goods manufacturing sector, which includes timber and plywood, is expected to decline in percentage of jobs by the year 2040. Average wage per job is highest in the manufacturing sector ($27,500 per year) and is expected to remain so. The nondurable goods sector, which includes paper production, is also expected to decline in percentage of jobs by the year 2040. This is also a high wage sector; the nominal average wage is currently $23,000 per year. The farming sector is expected to remain one of the smallest employment sectors. Average wage is the second to lowest in this sector after agricultural services ($12,000 per year). The government sector will decline by 0.03 percent per year to the year 2040. Wage rates are modest in this sector, averaging $19,000 per year.

Trends in Resource Allocation Priorities



The Social Assessment (following chapter) discusses the history of the Basin and the laws pertaining to the management and development of natural resources. From an economic perspective there are two lessons to be learned from the laws, policies, and regulations that guide Federal land stewardship. First, these laws, policies, and regulations document shifting public expectations about goods, services, and conditions derived from or found on public lands. Second, these laws, policies, and regulations have served to dictate resource allocation in those cases where markets either do not exist or where society has elected to intervene in markets (for example to lower prices).

The first lesson involves understanding that shifts in Federal policy through time have played their part in creating the political, legal, and ecologic conundrum faced by society, and its land managers, today. These shifts reflect changing societal views about what it wants from these lands. This discussion is evidence that society's priorities have changed over time—and by inference, will continue to do so.

RESOURCE CHARACTERIZATION

In this section we address specific resources relevant to FS and BLM administration, such as fish, minerals, range, recreation, special forest and range products, timber, and water, and include any available projections of supply and demand for each resource. The information presented in this section forms the basis for the economics of ecosystem management section at the end of this document that examines how different management directions might affect the bundles of goods, functions, and conditions produced by these ecosystems.

We have attempted to make the discussions of each resource group as consistent as possible. The differences in the detail of discussion for each resource are unavoidable and reflect many things. For example, a substantial amount of economic data are available for timber, but such information is virtually non-existent for special forest and range products (for example, floral greens, mushrooms, and huckleberries). For some resources, data were available for scattered locations but not consistently across the Basin. Unevenness in definition and methodology in data collection, between states for example, made it impossible to synthesize some information. Differences in the economic behavior of the resources exist—timber markets are well understood, recreation is largely not a market good, fisheries are a classic example of common goods. These differences result not only in uneven data, but in different traditions within the economic discipline of characterizing and evaluating resource questions.

Fish[17]

Understanding the economic systems relating to fisheries in the Basin is important because they are one of the resources the Charter specifies the ICBEMP to address. This section t orld in which fish populations are too low to support much commercial fishing but the consumptive and non-consump tive recreational value of the fish is substantial.

The Columbia River fishery story illustrates two important economic lessons. First, it demonstrates that a resource can be used at a rate that leads to its depletion. The same incentives for overuse are currently at work on under- or unpriced resources on BLM- and FS-administered lands. The second lesson is that economies are dynamic. Economic activities that dominate a society can disappear because of resource depletion, changes in technology, or changes in taste. Likewise, economic activities of minor importance today may become dominant activities in the future.

The Basin currently supports multiple fisheries enjoyed by American Indians and recreational and commercial interests. Today, in terms of total economic value, recreational fishing is more important than commercial fishing, and much of it takes place on public lands and waters. Recreational uses of fish are diverse and

[17] This section was written by Amy L. Horne based on Fluharty (1995).

pervasive, including fisheries for anadromous, resident, warmwater, and coldwater species; ice fishing; and fish viewing (recreational fishing will be covered in more detail in the "Recreation" section).

Fish spawned, reared, and cultured in the Basin contribute to in-river commercial fishing below Bonneville Dam and mixed stock fisheries off Alaska, California, Oregon, Washington and British Columbia, Canada. Commercial fishing above Bonneville Dam is currently far below historical levels and primarily reserved for the tribes by treaty (a small non-treaty fishery for white sturgeon exists). The tribes have commercial fisheries for steelhead, sturgeon, shad, and walleye and severely limited harvests of chinook and coho salmon. Compensation to the tribes for impacts of the dams on fisheries has reached a total of $90 million (nominal dollars) and can be expected to continue.

Altogether, the value of commercial fish harvests from the Basin is estimated at 12 million dollars per year, 93 percent of which is attributable to salmon, 5 percent to steelhead, and the balance to white sturgeon, shad, and walleye (table 6.5) (Fluharty 1995). A conservative estimate is that this results in between 600 and 1,200 direct jobs. More realistic estimates of lower income and less-than-full-time work would make this number higher (Fluharty 1995). On the other hand, the number of jobs may be overestimated because it is based on a 13-year average that includes a steadily downward trend since 1988; the 1995 value of the commercial fishery will probably be much below that. Today's commercial fishing values are lower than they would be if the fishery had been managed for strong stocks instead of for restricted catches (Fluharty 1995).

There are many resident native and non-native fish that contribute to fish values in the Basin. Some introduced species—both warm and

Table 6.5—Value of commercial fish stocks of the Basin, average annual in 1993 dollars, 1980 to present.

Species	Treaty commercial fishery in zone 6[1]	Non-treaty Columbia River landings	Estimated annual average value of Basin salmon caught in commercial ocean fisheries[2]	Total
	Thousand 1993 dollars			
Chinook	2,119	3,632	4,820	10,571

[3] No commercial sockeye salmon fishery has taken place since 1988.

coldwater fish—provide recreational activity but at the same time compete for habitat or directly prey on native resident species (Fluharty 1995). Recreation industries are evolving around some of these introduced species but in general they have received little management attention.

Historical Perspective

The history of fish in the Basin, and their economic significance, falls into three time periods. The first period is before significant commercial harvest began in 1860, when fishing was conducted primarily by Native Americans. The second period, from 1860 to 1980, is characterized by steadily dropping salmon populations, overfishing of some species, dam construction and operation, and loss of habitat; during this period the proportion of salmon caught by tribal members nearly went to zero while non-tribal commercial harvests climbed to near 100 percent. The third period, from 1980 to the present, is defined by a movement toward parity in the distribution of the shrinking salmon harvest within the Basin between tribal and non-tribal peoples, and the initiation of Basin-wide plans aimed at improving the salmon situation (fig. 6.9).

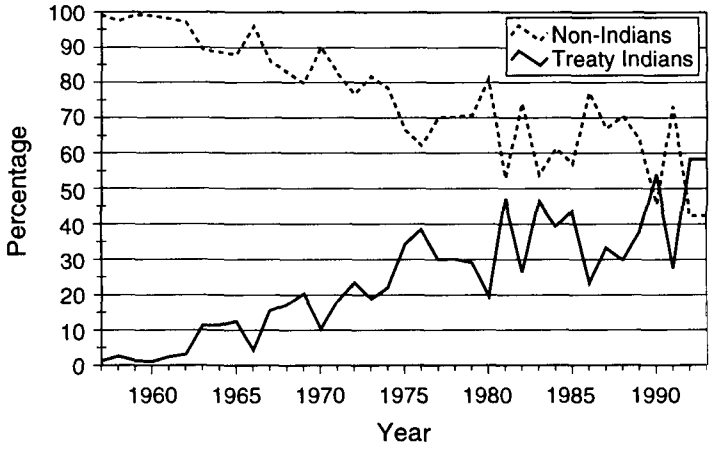

Figure 6.9— Distribution of Columbia River commercial landings of salmon and steelhead between tribal and non-tribal peoples, 1957-1993.

Between 1860 and 1980 the numbers of fish caught by Native Americans dropped precipitously from pre-commercial levels. In the mid-Columbia River[18] numerous conflicts occurred between tribal and non-tribal fisheries. Non-tribal fishwheel operators decreased tribal catch by occupying the best sites for harvesting salmon and by harvesting fish before tribes could. Dams and other habitat loss further diminished tribal fisheries, so that by 1958 their catch had dropped to only a few thousand fish.

With the treaty-fishing zone being located upstream from Bonneville Dam, and most of the fishery occurring below the Dam or in the ocean, questions about the meaning of the treaty language regarding the share of the harvest accruing to tribes were raised. In the Belloni and Boldt judicial decisions (*Sohappy v. Smith* 1969, *United States v. State of Washington* 1974), it was determined that fishing "in common" meant that fisheries management should ensure the harvests were split evenly (50% to 50%) between treaty and non-treaty fishing entities. These decisions helped set the stage for a new era of fisheries-management with vastly different allocation parameters and brought tribes to the fisheries management negotiation table for the first time.

Commercial fishing started on the lower reaches of the Columbia River and gradually expanded toward the ocean and upstream as competition for fish increased. Commercial harvest of Columbia River salmon increased rapidly after 1866 when new canning technology made it possible to process and ship salmon to distant markets (fig. 6.10). Harvest pressures intensified as new types of gear were developed. Harvests in the Pacific Ocean commenced in the late 1910s and early 1920s, putting tremendous pressures

[18] "Mid-Columbia River" is used here to refer to the main stem of the Columbia between the Bonneville and Chief Joseph Dams; "Lower Columbia River" refers to the river and its tributaries downstream of Bonneville Dam; "Upper Columbia River" refers to the mainstem east and north of Chief Joseph Dam.

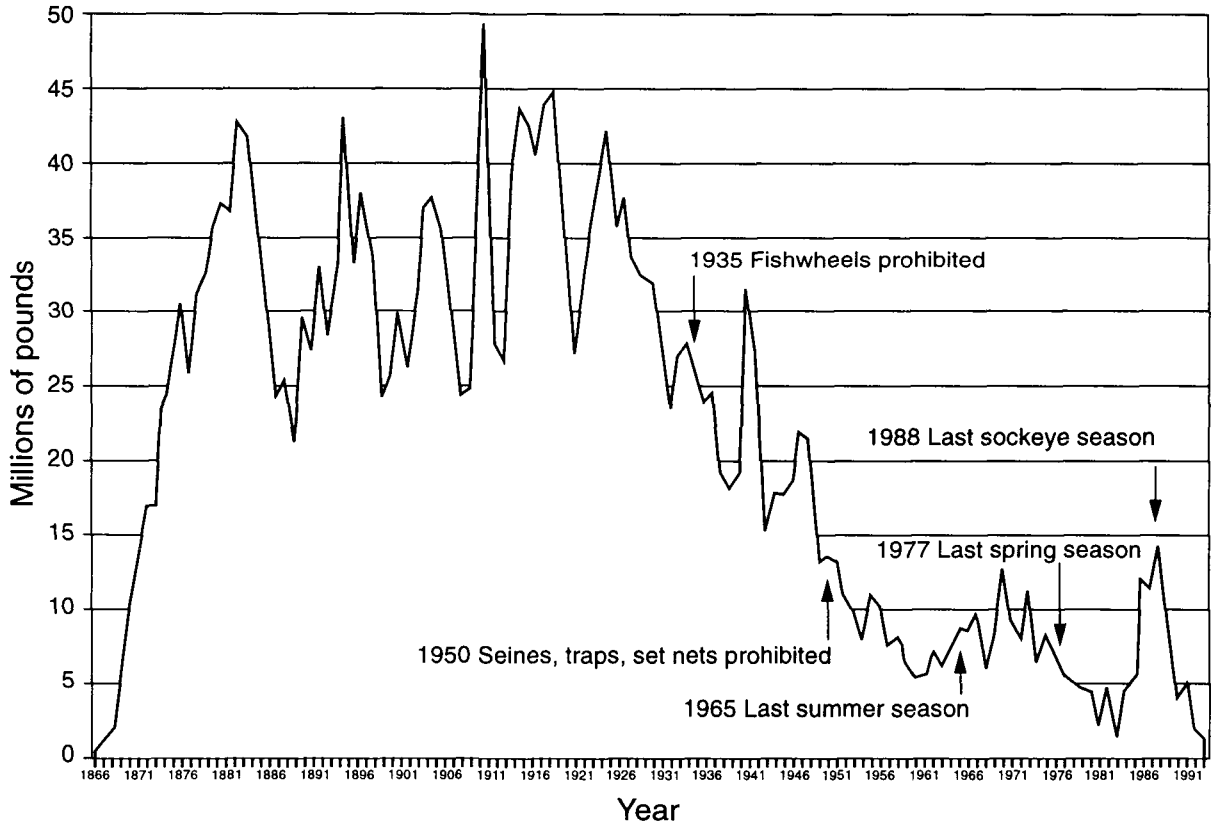

Figure 6.10— Annual commercial landings of salmon and steelhead from the Columbia River, in millions of pounds, 1866-1993.

on salmon populations spawning in the Basin. The Columbia River chinook salmon was the almost exclusive target species in the early salmon fisheries because of its abundance and value. With the decline in the chinook numbers, the fishery simply began to focus on other species. Total harvest of all salmon species fluctuated between 24 and 49 million pounds per year between 1880 and 1930, averaging 33.9 million pounds (Smith 1979). Salmon harvest from the Columbia River system dropped to about 23.8 million pounds annually in the 1940s; about 10.9 million pounds in the 1950s and to 1.2 million pounds by the early 1980s.

Before the development of the dams, distribution of in-river production of all species of salmon is estimated to have been 23 percent below the Bonneville Dam and 77 percent above (Lee 1993). By the late 1970s the production above Bonneville Dam (including hatchery production) had dropped to 42 percent, while salmon production below Bonneville Dam represented 58 percent.

Commercial catches of sturgeon began in 1884 and rose rapidly to 5.5 million pounds per year in the 1890s. Thereafter, sturgeon harvest dropped precipitously; in roughly a decade sturgeon was eliminated as a significant commercial species. The combination of high demand and value combined with the sturgeon's slow reproduction and growth rates required careful management—which the sturgeon did not receive. Subsequent construction of dams on the Columbia River severely restricted the movements of the large, old fish, hampering their ability to reproduce.

Shad were introduced into the Columbia River by 1876 (Wydoski and Whitney 1979). Dam construction on the mainstem of the Columbia River since the 1930s has benefited the shad by removing

Celilo Falls as a natural barrier and by creating the slower waters of the reservoirs. Shad have now extended their range to the Priest Rapids Dam on the Columbia River and into Idaho's Snake River. Since 1938, shad have supported a fishery ranging in size from 150,000 to 1.5 million pounds per year. The value of shad is low relative to other seafood because of low demand and high abundance. Management of this species is difficult because the fishery coincides with the higher value summer chinook salmon.

Another commercial fishery in the Basin is trout culture (Glude 1988). For over 100 years the Thousand Springs area of Idaho's Hagerman Valley has dominated the United States production of commercial rainbow trout with some 14 companies, 30 farms, and 16 fee-fishing pond operations.

Recreational demand for improved salmon and trout fishing in the Columbia River system has been a main factor driving restrictions on commercial gear and catch limits on the Columbia River, particularly after World War II (Smith 1974). Recreational catch grew from an insignificant amount at the turn of the century to a major component of the in-river fishery. Recreational fishing occurs throughout the range of salmonids in the Columbia River basin, but predominantly below the Bonneville Dam where fish quality is highest.

Chief targets for recreational fisheries in the Basin have been chinook, coho, and steelhead salmon. Rainbow, bull, and cutthroat trout have been the main native species taken along with the introduced brown trout (Ames 1966). Sturgeon sport fisheries are now strictly regulated to control harvests especially in Idaho and Montana; most recreational sturgeon fishing is now below Bonneville Dam. As opportunities for traditional sport fisheries have declined some fishing enthusiasts have shifted to catching introduced warm water species such as shad or walleye. Reservoirs and irrigation facilities have improved habitat for these species at the expense of native salmon and trout species preferred by more traditional Basin fishing enthusiasts.

Hatchery salmon production has not lived up to expectations, but it does supply a considerable proportion of the salmon caught in the Columbia River and the Pacific Ocean. The scale and cost of the hatchery operations by tribes, states, power companies, and federal agencies has been large. Between 1938 and 1975, approximately $400 million was spent on fish passage facilities at dams, hatcheries, and spawning channels. A series of 21 hatcheries, 86 fish ladders, and spawning-habitat restoration projects were initiated in 1949, which cost an additional total of $84 million by 1975 (Smith 1979).

The value of the recreational salmon and steelhead fishing supported by the Basin was about $9.7 million per year (1987-1991). Fish caught in the Columbia River represented 81 percent of this value and the rest were caught in the Pacific Ocean off the United States (Alaska, Washington, Oregon, and California) and Canada. Three-quarters of this value ($7.3 million) was contributed by recreational steelhead fishing in the Columbia River. Most of the rest of the value lies in recreational fishing for fall chinook caught either below Bonneville Dam or in the Pacific Ocean.

Future Fish Valuation Issues

Future economic values of fish in the Basin depend on demographic trends, social preferences, outcomes of a variety of public policy debates, and biogeophysical events and trends. As the population in the Pacific Northwest region continues to grow more people will participate in fishing in the Basin.

If there are continuing losses of salmonids, the relative importance of other species is likely to increase. Coldwater fishing opportunities are notable in the Basin, particularly in headwater streams supporting native trout but also in lakes and streams where introduced coldwater species and hatchery stocks constitute the bulk of the fish. Warmwater species are also likely to play an increasing role in providing recreational opportunities.

Pumping ground water in Idaho's Snake River Valley may also pose a threat to riparian ecosystems and fish. A number of rivers are over-subscribed for water withdrawals, leaving little for fish at the requisite time. It remains to be seen whether resolution of water rights issues on a state-by-state basis will benefit fish and wildlife. Without such consideration, fish are likely to have an increasingly difficult time, and so will their commercial, tribal, and recreational usage.

Minerals[19]

Three major components of the mining industry in the Basin are covered in this section, metallic minerals, phosphate, and aggregates (sand, gravel, and crushed stone), each of which has distinct economic characteristics. This section begins with a description of minerals activity in the Basin. For metallic minerals and phosphate, activity is minor in spatial scale but significant in national and international commodity markets. Aggregate mining is more widely distributed throughout the Basin and lower in value; aggregates are primarily traded in local markets and used to construct buildings and infrastructure associated with human populations. Although mining is important to jobs and income in a few communities in the Basin, when compared with a large, diverse, and growing economy it represents only a minor share of gross state product (GSP). Effects of past metal mining are discussed after mineral activities. Mining for metals has caused wide-spread and long-term environmental hazards in some parts of the Basin (most notably the Clark Fork River and Smelterville in Kellogg, Idaho).

The future of minerals activity in the Basin is addressed in the last section. The distribution of activity relating to mineral exploration and development is dependent on the locations of deposits, which are restricted to specific geographic areas for metals, minerals, and phosphate, but are more widely dispersed for aggregates. Whether activity will occur in the future will depend on a number of factors including the minerals present and their grade, global prices, technology, and access. Most of these factors, except for access, will not be affected by BLM or FS policy or regulation.

[19] This section was written by Michael Zientek and Tom Frost, U.S. Geological Survey, based in part on a background report prepared for the ICBEMP by the U.S. Bureau of Mines.

Overview of Recent Minerals Production

The mineral industry in the Basin is localized in a few counties; consequently, its contribution to regional employment is small. Within the industry, however, the types and values of minerals produced play an important role in national and global spheres (tables 6.6 and 6.7). Phosphate deposits in Caribou County, Idaho, primarily in the Snake Headwaters Ecological Reporting Unit (ERU), account for 4 percent of the world's phosphate production and over 12 percent of the national output. Gold production in Montana, Idaho, and Washington accounts for 11 percent of national and 1.5 percent of world production. Silver production in Idaho and Montana represents 30 percent of the Nation's and 4 percent of the world's silver production. Similar comparisons for lead, copper, and zinc cannot be made because the data are combined or withheld for confidentiality.

Two mining districts in the Basin, Butte (Upper Clark Fork ERU) and Coeur d'Alene (Lower Clark Fork ERU), contain world-class deposits that have contributed an important share of the Nation's copper and silver production (table 6.8). Mineral deposits of such size are quite uncommon and can significantly affect the world supply of minerals (Singer 1995). The Coeur d'Alene and Butte mining districts have contributed more than 90 percent of all the base-metal and silver produced in the Basin. Mines in the Coeur d'Alene district consistently rank among the top ten for silver and lead production in the country. The three largest hardrock gold-producing districts, Butte, Republic, and Boise Basin (in the Upper Clark Fork, Northern Glaciated Mountains, Central Idaho Mountains ERUs, respectively), are responsible for over 38 percent of the total production from the Basin. Historically, several deposits have been among the top 20 deposits in the United States for gold, zinc, and copper production.

Table 6.6—Selected minerals production in the world, the United States, four northwest states, and Nevada;[1] importance of Basin minerals production at international and national scales.

Commodity	World production	United States production	U.S. Percentage of world production	World rank	World reserve base	U.S. reserve base	U.S. percentage of base	World rank

Nonfuel metallic and nonmetal mineral commodities are not distributed uniformly across the Basin, so that while mining is locally important it is only a minor factor in state-wide economic statistics (figs. 6.11 and 6.12). Mineral deposits tend to occur in clusters or belts that reflect the underlying geological processes that controlled their distribution. Occurrences of mineralization are not equally valuable. Even though there are thousands of prospects in the Basin, a few world-class deposits account for most of the production and resource base in the region.

These mineralized terranes and world-class mineral deposits bestow a comparative economic advantage for the exploration and development of these resources in some areas. Twenty of the 100 counties within the Basin accounted for more than 90 percent of the Basin's nonfuel mineral production value over the period 1980 to 1992 (fig. 6.13). The top six counties (Caribou and Shoshone, Idaho; Silver Bow and Lincoln, Montana; Humboldt and Elko, Nevada) account for nearly 70 percent of the mineral production value in the same time period. Only two of these counties (Lincoln, Montana and Shoshone, Idaho), however, are entirely within the Basin. In the top ten mineral producing counties in the Basin, mining employment ranged from 0.63 to 13.22 percent of total employment in 1992 (table 6.9). Being a high wage sector, the percentage of total county earnings from the mining sector is more dramatic, ranging from 1.53 to 36.46 percent, and averaging 16 percent in 1992.

Across the Basin, there are 180 mining and mineral processing sites in operation, 11 under development, and 10 maintained on standby status (fig. 6.14). The value of production from these sites in 1992 was approximately $2.7 billion. These numbers do not include production of aggregate. Only 18 sites, which had a total production value of more than $600 million in 1992, are considered large (table 6.10).

In 1990, the contribution of mining, including aggregates, to the GSP of the Basin economy was estimated to be 4.2 percent. The majority of this contribution was from nonfuel minerals, significantly above the share of nonfuel minerals in the GNP (approximately 1%). Mineral fuels contribute less than one quarter of the mining contribution. The mining sector's contribution to employment in Montana, Idaho, Washington, and Oregon ranged from about 0.1 percent to 1.5 percent of the totals. Mining earnings range from 0.2 percent to 3 percent of the totals for these states.

Metals production is the most important component of nonfuel minerals in the Basin, representing approximately 75 percent of the total value between 1982 and 1990. In contrast, metals production in the Nation only accounted for 37 percent of the value of nonfuels mineral production from 1989 to 1991. Most of the value in the Basin came from the production of gold; also important were silver, copper, molybdenum, magnesium, lead, and zinc. The value produced by each of these metals cannot be reported because of confidentiality.

The total average annual value of nonfuel mineral production in Idaho, Montana, Washington, and Oregon increased between 1959 and 1991 by 35 percent, in real terms, to $1.6 billion. In the 1980s, the value of mineral production decreased by about 7 percent in real terms. This decrease reflects a lengthy and deep recession in the minerals industry which prompted closures of mines in the Coeur d'Alene mining district and reduced production from deposits at Butte. The percentage of mining in the GSPs of Idaho, Montana, Oregon, and Washington has largely declined over time, because other sectors have grown at a faster pace.

Remediation Costs for Past Mining

The U.S. Bureau of Mines estimates that there are nearly 14,000 inactive or abandoned mining sites in the Basin, of which 164 sites have a high potential for environmental hazard. Another 190 sites were classified as having possible potential for environmental hazard. Expenditures required to remediate these sites will contribute significantly to jobs and income in some regional economies, if money is found to pay for remediation.

The estimates of the costs to remediate chemical hazards associated with mining are inconsistent, some separated by orders of magnitude. In 1988, the General Accounting Office (GAO) estimated that 424,049 acres of Federal land affected by hardrock mining in 11 western states were unreclaimed. The cost of reclaiming the abandoned 281,581 acres was estimated to be $284 million. The Western Governor's Association Mine Waste Task Force stated the cost of remediation would be $315 million in Idaho, $912 million in Montana (including Superfund sites), and up to $77 million in Oregon. The EPA estimates that it will cost $210 million to mitigate the Bunker Hill Superfund site in Idaho; at least $53 million has been spent so far in remediation efforts in the Clark Fork Basin in Montana.

Future Mineral Development

Discovered metal deposits in the Basin, primarily in the Butte and Coeur d'Alene mining districts, contain significant percentages of the world's discovered resources for copper (3%), lead (2.5%), and zinc (1%). Nationally, deposits in the Basin account for 15 percent of the copper, 13 percent of the lead, and 6 percent of the zinc. Twelve to 73 percent of these discovered resources remain to be produced.

Metallic mineral deposits—The short term is defined as the time it takes to put a mineral deposit into production once it is discovered, about 10 years. Figure 6.14 shows the location and operational status of 141 significant metallic mineral deposits in the Basin. The map reveals historical and current patterns for mineral development in the region as well as where activity may occur in the future. Eighteen metallic mineral deposits are currently undergoing feasibility studies and could be put into production in the next 10 years; in addition, there are 22 deposits in production, under construction, or on standby. Another 14 deposits are not currently economic to mine; summary statistics for these sites are in table 6.11.

Long-term forecasts of minerals activities require probabilistic estimates of new discoveries. Quantitative estimates for undiscovered metallic resources in the Basin were developed by first delineating 97 tracts in which 25 metallic mineral deposits might occur. Within these "permissive" tracts, areas favorable for undiscovered mineralization were delineated when there was indication of mineralization. The final step was to estimate the probability of the number of undiscovered deposits present and to simulate the amount of undiscovered metal. An average of 84 undiscovered deposits was

Table 6.11—Activity status of discovered deposits of base and precious metals in significant mineral deposits in the Basin, 1995.[1]

Resources	Gold	Silver	Copper	Lead	Zinc	Cobalt	Molybdenum
	Metric tons of metal						
Mines in production or under construction	303	4,666	1,282,523	992,322	108,067	--	342,376

Total	785	23,392	7,871,878	1,052,423	631,598	17,418	2,195,269

[1]Modified from Zientek and others (1995).

estimated to be present for all of the 25 deposit types. Statistics summarizing the amount of undiscovered metallic mineral resources are presented in table 6.12.

Economic activity associated with undiscovered metallic mineral deposits has high likelihood in all ERUs except the Southern Cascades, Upper Klamath, and Upper Snake (fig. 6.15). An economic analysis was used to forecast the likelihood of supplying minerals from these undiscovered resources (table 6.12). The economic potential of these resources is estimated as the proportion that could be produced under specified economic and technological conditions. The analysis considered only those deposit types currently thought to be exploration targets.

At current metal prices, about 12 undiscovered deposits are economically feasible. If developed at the same time, these mines could generate annually almost 11,000 jobs, $770 million regional output, and $326 million in income. If prices double, about 33 deposits would become economically feasible to mine. These mines could generate annually about 19,500 jobs, $1.4 billion regional output, and $592 million in income.

Developing a long-term economic forecast for mineral development in the Basin requires combining three pieces of information: the likelihood that undiscovered resources will be developed, inactive mines, and discovered resources that are either undeveloped, on standby, or in development. Whether mineral resources are developed depends on the quality and quantity of the resource, market conditions, improved technology for low-cost extraction and processing techniques, and, to the extent the deposits are on Federal land, Federal land-use policies. The combination of these factors creates much greater uncertainties in the long-term forecast compared with the short-term. The results of the long-term forecast are illustrated in figure 6.16 and table 6.13. The map shows areas whose undiscovered resources are favorable for development activities. It also shows areas of known significant deposits, both producing and undeveloped, around which mineral activity may be expected in the long term. General patterns for minerals activity include:

- A northeasterly trend of areas that may be favorable for long-term mineral development extends from southeastern Oregon through central Idaho and into southwestern and central Montana. The most economically attractive targets are gold and silver in large, low-grade, bulk mineable deposits, and deposits of copper and cobalt in central Idaho.
- In the western part of the Northern Glaciated Mountains and North Cascades ERUs, underground mining for gold and silver has a long history and will likely continue in the short term. In the long term, more emphasis will be placed on developing bulk-mineable open pit mines.
- A northwesterly trend of areas with considerable base metal resource extends from southwestern Montana through northern Idaho and into northeastern Washington. This includes the Butte and Coeur d'Alene mining districts, which account for the bulk of past production of copper, lead, zinc, and silver in the Basin. It also includes significant copper-silver deposits in northwestern Montana and lead-zinc deposits in northeastern Washington.

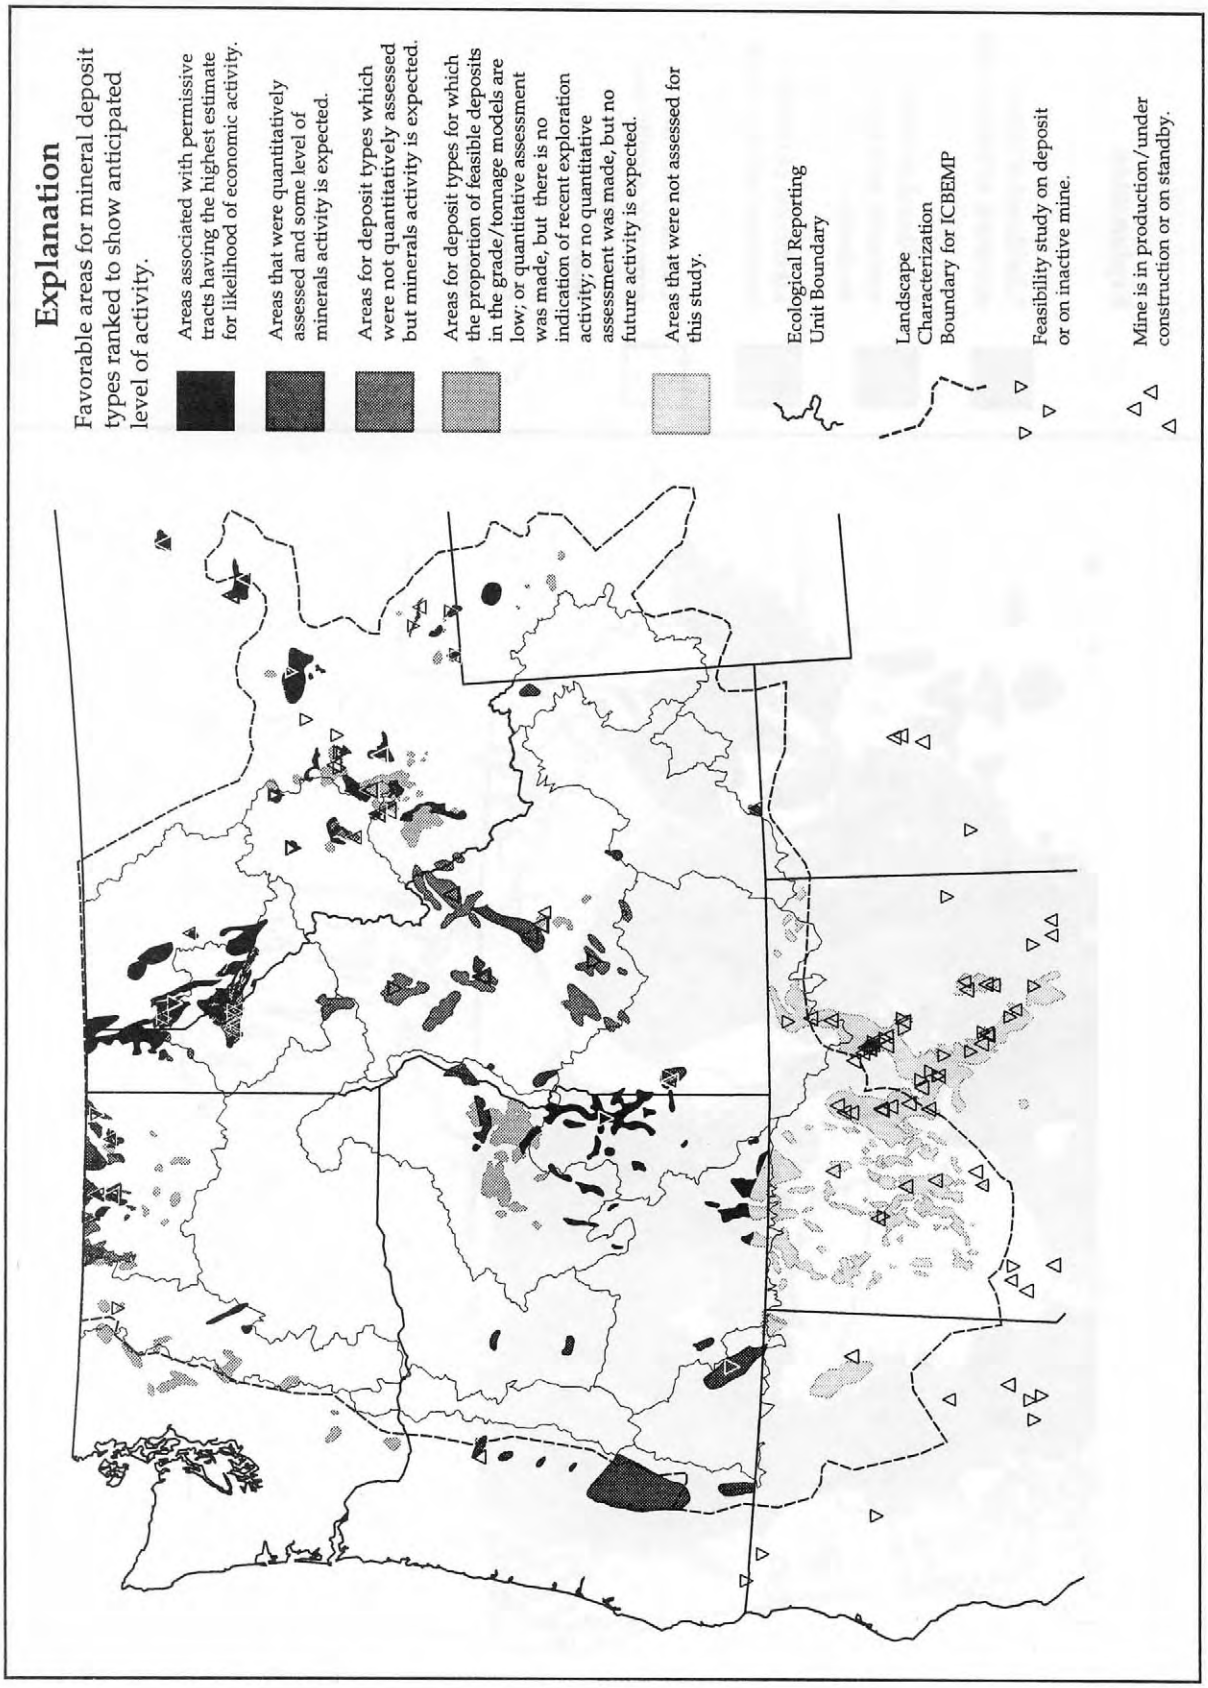

Figure 6.16— Likelihood of base, precious, and ferroalloy metals activity in the Basin.

Table 6.13—Potential metallic mineral and phosphate resources in each Ecological Reporting Unit (ERU) in the Basin.

ERU	Metallic resources -- base and precious metals		Non-metallic resources -- phosphate	
	Short-term	**Long-term**	**Short-term**	**Long-term**
Southern Cascades and Upper Klamath	Southern Cascades: No significant base, precious, or ferroalloy deposits are known. If a discovery were made, it is unlikely that the deposit would be in production in the next 10 years. Upper Klamath: No sites with *significant production were identified;* however, a recently discovered gold deposit is undergoing feasibility studies.	The Southern Cascades, Upper Klamath, and Upper Snake are the only Ecological Reporting Units in which permissive tracts for undiscovered resources with a high likelihood of economic activity do not occur. Favorable areas for undiscovered mineralization occur in the Upper Klamath ERU.	None	None
Snake Headwaters and Upper Snake	Snake Headwaters: No significant base, precious, or ferroalloy deposits are known. If a discovery were made, it is unlikely that the deposit would be in production in the next 10 years. Upper Snake: Minor gold and silver production and resource identified in the Champagne deposit, Butte County, Idaho. However, no other significant deposits of base, precious, or ferroalloy metals were identified. For most of the area, no additional short-term metallic minerals production activity is anticipated.	The Southern Cascades, Upper Klamath, and Upper Snake are the only Ecological Reporting Units in which permissive tracts for undiscovered resources with a high likelihood of economic activity do not occur. Favorable areas for undiscovered mineralization are small proportion of both ERUs (≤ 1 percent).	Phosphate deposits that can be mined by open-pit methods are located mostly in the Snake Headwaters ERU, and in adjacent parts of the Upper Snake ERU. Seven major active open-pit mines in the southeast Idaho phosphate district are the Conda, Henry, Maybe Canyon, Wooley Valley, Enoch Valley, Mountain Fuel, and Smokey Canyon mines.	Large-scale open-pit mining and processing of phosphate ore probably will continue into the long-term future in the Snake Headwaters and Upper Snake ERUs.

Table 6.13 (continued).

ERU	Metallic resources -- base and precious metals		Non-metallic resources -- phosphate	
	Short-term	**Long-term**	**Short-term**	**Long-term**
Northern Great Basin	No significant base, precious, or ferroalloy deposits are known. If a discovery were made, it is unlikely that the deposit would be in production in the next 10 years.	Includes permissive and favorable tracts for undiscovered resources with a high likelihood of economic activity.	None	None
Columbia Plateau	Minor historic gold production from the Pierce City placer deposit in Clearwater County, Idaho. However, no other significant deposits of base, precious, or ferroalloy metals were identified.	Includes permissive tracts for undiscovered resources with a high likelihood of economic activity. Favorable areas for undiscovered resources are a small proportion of the ERU (<1 percent).	None	None
Blue Mountains	Numerous sites with significant historic mineral production of base and precious metals. Essentially all of the identified resources are now associated with the Red Ledge deposit, which is within Hell's Canyon National Recreation Area. Therefore, no short-term minerals activity is anticipated in this region. Exploration around the large number of inactive mines could find extensions to these deposits or develop additional resources based on different mining and beneficiation methodologies. However, no discoveries have been reported that would indicate short-term minerals production.	Includes permissive tracts for undiscovered resources with a high likelihood of economic activity. Favorable areas for undiscovered resources are a significant proportion of the ERU.	None	None

Table 6.13 (continued).

ERU	Metallic resources -- base and precious metals		Non-metallic resources -- phosphate	
	Short-term	**Long-term**	**Short-term**	**Long-term**
Central Idaho Mountains, Lower Clark Fork, Northern Cascades, Northern Glaciated Mountains, Owyhee Uplands, and Upper Clark Fork	Significant past and current production from the following counties: Central Idaho Mountains - Custer Co., Idaho Lower Clark Fork - Shoshone Co., Idaho Northern Cascades - Chelan Co. Wash. Northern Glaciated Mountains - Ferry and Stevens, Cos., Wash. and Lincoln Co., Mont. Owyhee Uplands - Owyhee Co., Idaho and Elko Co., Nevada Upper Clark Fork - Silver Bow Co., Mont. All ERU's contain significant discovered resources of base, precious, and ferroalloy metals and deposits that are currently undergoing feasibility studies.	Includes permissive and favorable tracts for undiscovered resources with a high likelihood of economic activity. Favorable areas for undiscovered resources are a significant proportion of the ERU.	The Montana phosphate district, located in the Upper Clark Fork ERU, is a relatively minor producer of phosphate rock from underground mines. The Centennial underground mine is located on the Idaho-Montana border, near the northern margin of the Upper Snake ERU.	Smaller-scale, underground mining of phosphate ore probably will continue in the Upper Clark Fork ERU.

Metallic mineral deposits will be available for discovery and exploitation for decades to come. Compared with the 775 metric tons of gold that already have been produced from the Basin, estimates of the amount of gold remaining in undiscovered, conventional deposits range from 822 to 3,116 metric tons. Estimates are that at present, 785 metric tons of discovered gold remains to be developed. Estimates for other commodities are summarized in tables 6.11 and 6.12. Conservative measures of the frequency distribution (0.95 and 0.90 quantiles) of copper, zinc, gold, and silver contained in undiscovered deposits in the Basin are comparable to the amount identified in discovered deposits; measures for lead and molybdenum are much lower than the identified resource base. Average values of the frequency distributions for gold, silver, copper, lead, and cobalt contained in undiscovered deposits are two to five times higher than the resources remaining in known deposits; the same measure for zinc is 15 times that in the known resource base.

Phosphate—The Western Phosphate Field underlies an area of about 130,000 square miles in southeastern Idaho, western Montana, western Wyoming, and northern Utah (see fig. 6.12). Although resources in the Western Phosphate Field are vast, the amount that can be economically mined is limited. Phosphate deposits that can be mined by open-pit methods are located mostly in the Snake Headwaters and adjacent parts of the Upper Snake ERUs. Seven major active open-pit mines are in operation in southeastern Idaho. The Montana phosphate district, located in the Upper Clark Fork ERU, is a relatively minor producer of phosphate rock from underground mines. The Centennial underground mine is located on the Idaho-Montana border, near the northern margin of the Upper Snake ERU. Three major phosphate treatment plants are located in Soda Springs, Idaho; two others are located in Pocatello, Idaho. A vanadium-recovery plant is also located in Soda Springs (Bennett and Gillerman 1994).

Large-scale open-pit mining and processing of phosphate ore probably will continue into the long-term future in the Snake Headwaters and Upper Snake ERUs. Smaller-scale, underground mining of phosphate ore probably will continue in the Upper Clark Fork ERU. Reserves of economically exploitable phosphate ore in southeastern Idaho are estimated to be 1 billion metric tons of ore that average 24.5 percent P_2O_5 (Kraus and others 1984). The Montana phosphate district has an estimated resource of 600 million metric tons of ore that average 24 percent P_2O_5. Recent total annual production from southeastern Idaho has averaged 5 million metric tons a year (U.S. Bureau of Mines 1993b). Assuming production continues at similar rates, the known ore represents at least 200 years of future mining and processing. Over time, mining probably will shift to lower-grade and/or deeper ores, as warranted by changing technologies, economic conditions, and competitor activities.

Aggregate—Natural aggregate (sand and gravel, or crushed stone) is used primarily in construction and repair of infrastructure—buildings, roads, bridges, runways, railways, dams, canals, and sewer systems. Aggregates are primarily used in urban areas and transportation routes; markets generally are local in order to minimize transportation costs. The 1980-1992 cumulative value of sand-and-gravel and stone produced in the Basin was $1.3 billion, or 10 percent of the value of the total mineral production of the region.

About 11 tons of stone, sand, and gravel are produced per person per year in the seven states that compose the Basin. If this rate continues and population increases as predicted, total production could rise from 46.4 million tons in 1992 (from 449 operations) to over 100 million tons per year (from about 900 operations) by the year 2050. Deposits of sand and gravel form more slowly than the rate at which they are being depleted in areas of high demand. In the long term, sand and gravel deposits will be depleted or built over in urban areas, and aggregate production will shift toward crushed rock as it has in eastern and midwestern states (Langer and Glanzman 1993).

Range[20]

Cattle grazing has been an important part of the Basin's economy since just after the Civil War (Schwantes 1989). It has also been a lightning rod for debate about the stewardship of public lands both in the Basin and elsewhere in the West. The FS began regulating grazing on National Forest land in 1905 and the passage of the Taylor Grazing Act (1934) extended range regulation to the rest of the public domain.

Starting in the 1970s efforts were made to address concerns of local ranchers, agencies, and the public about inaugurating multi-resource and interdisciplinary management on BLM and FS rangelands (Quigley and others 1989). Reflecting stewardship demands for "more than just grazing" on the public lands, these efforts addressed forage production, livestock use, wildlife habitat and riparian enhancement, environmental quality, rural community stability, and development of diverse and healthy rural economies.

Critics of cattle management on western public lands state that public agencies have become captive to the livestock industry, that current use levels are eroding public lands, encouraging exotic plants, displacing native plant and animal species, and that agencies charge fees that are far below market values (Ferguson and Ferguson 1983). These and other critics have called for wholesale changes in management of the public range, tighter Federal controls, and reduced grazing. Karl Hess, Jr. (1992, 1995) provides another viewpoint and argues that public range stewardship should employ market incentives rather than rely on government policies, laws, and regulations.

This section briefly characterizes the role of livestock in the Basin and the nine BEA regions and evaluates livestock dependence on forage on lands managed by the FS and BLM. It also provides background information on grazing and on Federal rangelands in the western United States. Finally, this section examines contempory economic issues and the current projections of livestock production.

Western Range Overview

The productivity of western rangelands is extremely variable; the better desert sites in Oregon and Washington produce up to 250 pounds of forage per acre, while grasslands may produce up to 5,000 pounds per acre (Joyce 1989). Rangeland condition has changed dramatically throughout the western states since Europeans first appeared. Misuse and overuse caused range conditions to be most degraded around the turn of the century; range condition has been improving in most areas since the 1930s (Joyce 1989).

In 1987, 57 percent of the 22.0 million acres of Oregon rangeland was Federally owned (12.6 million acres) and 43 percent of the acreage was non-Federal (9.4 million acres). Washington rangeland was 25 percent Federal (1.9 million acres) and 75 percent non-Federal (5.6 million acres). We do not have similar data for the other individual states in the Basin, but in the eight states of the Rocky Mountain region (Montana, Idaho, Wyoming, Utah, Nevada, Colorado, Arizona, New Mexico), 336 million acres (of a land base of 553 million acres) is rangeland. Of the 336 million acres, about half (167.4 million acres) is federally owned. The BLM administers 125.5 million acres; the FS 33.5 million acres; and other Federal agencies 8.4 million acres.

According to the *Rangeland Reform '94 Draft EIS* (U.S. Department of Interior 1994a), there are about 26,900 permits to graze livestock on Federal rangelands held by 22,350 livestock operators nationwide. In the 11 western states in which Federal rangeland is concentrated,[21] permittees

[20] This section was written by Christopher E. DeForest, based in part on the background work of Leslie Frewing-Runyon, Economist, Bureau of Land Management, Oregon State Office, Portland, OR.

[21] These 11 western states are Oregon, Washington, California, Idaho, Montana, Wyoming, Nevada, Utah, Colorado, Arizona, and New Mexico.

and lessees make up 22 percent of total beef producers. Beef cattle producers with Federal permits make up about 3 percent of the 907,000 producers in the 48 contiguous states. Permitted use on Federal lands makes up about 7 percent of beef cattle forage and about 2 percent of the total feed consumed by beef cattle in the 48 contiguous states. As for sheep, the roughly 4,600 sheep producers with Federal permits make up about 19 percent of total sheep producers in the 11 states in which Federal rangeland is concentrated.

Dependency on Federal Forage

A perennial question is to what extent ranchers are dependent on Federal forage. In this document, "dependency" is defined as the portion of total feed consumed by livestock provided by permitted use of FS and BLM lands. Total feed requirements were calculated assuming a cow needs 12 animal unit months (AUMs) per year and a sheep needs 2.4 AUMs. An AUM is the amount of forage required to sustain one cow, five sheep, or five goats for one month; forage includes grazed forage, hay, crop residue, silage, or grain. The lack of consistent, region-wide, county-level data required us to assume that cattle and sheep inventories reported by the Census of Agriculture are within a single county for the whole year. This would not be the case if Federal pastures are in a different county than the associated base ranch. Another complication is that many operators have multiple land holdings and permits, and may transfer livestock to other counties or states in the winter.

The dependency of the livestock industry on BLM and FS forage varies from 1 to 11.9 percent of total forage among the BEA regions, with an average of 7 percent (table 6.14). These percentages reflect the dependency of the livestock industry on BLM and FS forage. The numbers would be higher if they included only those operators holding Federal permits or reflected the seasonal importance of Federal forage (see below). Cattle dependent on BLM and FS AUMs average 2 percent of total agricultural sales across the Basin. (We discuss the livestock industry relative to agriculture because it is a part of that sector.) BEA regions in which cattle sales represent higher than the average percent are Redmond-Bend (2.7%), Idaho Falls (2.9%), and Boise (5.4%).

Seven counties in the Basin had over 30 percent dependency on FS and BLM AUMs: Skamania, Washington (48%); Camas, Idaho (39%); Humboldt and Elko, Nevada (38% each); Custer and Clark, Idaho (36 and 34%, respectively); and Chelan, Washington (33%). Of the 100 counties in the Basin, 67 counties had under 10 percent dependence on FS and BLM forage. On average, one cow or one sheep got 3 percent of its feed from FS or BLM permit lands. Only five of the counties with over 10 percent dependence on Federal grazing were large producers of cattle and calves (over $25 million). Most of the counties identified as highly dependent on Federal forage had small sales of cattle and calves, suggesting that the livestock industry in those counties may be marginal.

Using annual AUM data obscures the seasonal nature of shifting cattle or sheep between pastures during the year. Much of the public rangeland is at higher elevations and is traditionally used for spring or summer grazing while the richer private lands lie fallow or are used to grow winter feed. The degree of seasonality for BLM- and FS-administered lands and other Federal lands varies widely between states (table 6.15). Although the BLM, FS, and other Federal lands are grazed mostly in the spring and summer, they also receive considerable use in the fall and winter. Thus the seasonal availability of some types of rangeland may constrain livestock production more than numbers of permitted AUMs.

This estimate can be calculated from assumptions about the seasonal pattern herd size and extent of substitute feed during different grazing seasons. By assuming the average seasonal pattern shown in table 6.15, a constant annual herd size, and that

Table 6.14—Importance of agriculture and grazing (a component of agriculture) to Bureau of Economic Analysis (BEA) on Bureau of Land Management (BLM) and Forest Service (FS) land to economies of the Basin, by BEA region.

BEA region	Agriculture labor income as percent of total labor income	Value of agricultural products sold ($millions)	Cattle-calf sales as percent of total agricultural product sales	Dependency on FS-BLM Animal Unit Months (AUMs)	Percent of total agricultural sales dependent on FS-BLM AUMs
	Percent	1992 dollars	Percent	Percent	Percent
Tri-Cities	12.3	2,196	22.3	1.4	0.3

Federal feed losses could only be offset by 10 percent during the spring and summer periods critical to dependent ranching operations, each reduction in Federal AUMs affects ranching operations by an additional 20 percent, which corresponds to a factor of 1.2.

It is often argued that private herd sizes are limited by availability of spring and summer Federal forage. This argument assumes that livestock operations would not be able to find alternative feed sources if the Federal grazing program were reduced. While this might be true in the short run, in the long run operators may adjust to reduced Federal range permits in a number of ways depending on relative costs. Adjustments might include shifting the timing and use of their base property, changing herd size, or buying additional feed. Another adjustment might be to change the type of operation from "cow/calf" to "stocker/feeder."

Permit Issues

There are a number of issues that surround the permit system used in Federal range management. These issues are a central focus of the Rangeland Reform EIS (U.S. Department of Interior 1994b) and those results are used in this section to describe some of the permittee issues. One side note, the Rangeland Reform EIS reports 1992 dependency levels for permitted cattle and sheep herds, by state (table 6.16). Their definition of dependency is different from ours and represents the dependency of only those ranchers who hold Federal grazing permits; it excludes the majority of ranchers who have no access to Federal forage. This accounts for the difference from the much lower figures reported in table 6.15.

A basic characterization of the holders of FS or BLM grazing permits are that, on average, they had much bigger operations and were more profitable per cow and per ranch than non-permittees (tables 6.17 and 6.18) (U.S. Department of Interior

Table 6.15—Seasonality of grazing allotments, by state, on Bureau of Land Management (BLM), Forest Service (FS) and other Federal[1] land, 1994.

State	Spring		Summer		Fall		Winter		Not Seasonal[2]		Total
	Number	Percent	Number	Percent	Number	Percent	Number	Percent	Number	Percent	Number

1994a). Federal grazing permittee per-cow costs and receipts were significantly lower than for non-permittees. Non-permittee cash expenses were $106 per cow higher than permittee costs (31%); permittee cash receipts were $65 lower than non-permittee cash receipts (13%). The lower expenses were due chiefly to lower costs for feed; capital expenditures per cow were also lower (U.S. Department of Interior 1994a). Federal permittees also averaged almost nine times as many sheep as non-permittees (112 sheep versus 13 sheep). Permit acreage and AUMs are skewed heavily toward the largest permit holders (U.S. General Accounting Office 1992, 1993). The 1,000 largest BLM permit holders (out of 22,058 permits, covering 163.3 million acres in 16 western states) had 50.3 percent of the AUMs in 1991, while the 1,000 smallest had 0.04 percent. For FS land, the 1,000 largest permittees (of 8,206 in FS Regions 1 to 6) controlled 63 percent of the AUMs while the 1,000 smallest had 0.3 percent. The bulk of the benefits from the subsidized Federal program went to a small number of individuals, corporations, and partnerships.

Table 6.17—Cow-calf production cash costs and returns for Federal grazing permittees and non-permittees in ten western and Great Plains states, 1990.

Item	Non-permittees	Permittees	Non-permittees	Permittees
	..... Dollars per ranch		..... Dollars per cow

Table 6.18—Comparison of Federal grazing permittees and non-permittees ranch and herd size, 1990.

	Number of ranches in sample	Average herd size	Percent of operations with:		
			Fewer than 100 cows	100-499 cows	500 or more cows
Permittees	6,678	221	33.9	56.9	9.2
Non-permittees	49,658	93	61.6	35.1	3.3

Source: U.S. Department of Interior (1994a).

A 1986 General Accounting Office report found that about 76 percent of the permittees with grazing permits on BLM-administered lands were individuals, but that they accounted for only 54 percent of the AUMs. Another 11 percent were corporations that controlled 29 percent of the AUMs from BLM forage. Another 8 percent of the permittees were partnerships that held 7 percent of the AUMs. The same report found that small herds (under 100 animals) accounted for half the permits but only 10 percent of the AUMs; while large herds (500+ animals) accounted for 15 percent of the permits and 58 percent of the AUMs.

Having a Federal grazing permit allows the holder to graze livestock on Federal lands, typically at below-market rates. Permits also confer value in two other ways; "as a general rule, all else being equal, a ranch with a Federal grazing permit is worth more than a ranch without a permit" (U.S. Department of Interior 1994a). One hidden value has to do with transferability of grazing permits. When a ranch with a BLM or FS permit is sold, the permit is usually reissued to the new owners, provided they agree to meet regulatory requirements and the terms and conditions of the permit. As a matter of law, the issuance of grazing permits creates no right, title, or interest in the Federal lands. However, as a matter of practice, because grazing permits are usually reissued to the new owner, they attach value to the base property. The value of the permit at least partly reflects the capitalized value of the subsidy, the difference between the Federal grazing fee and the competitive market rate that could be charged for Federal forage (U.S. Department of Interior 1994a). Correspondingly, changes in Federal grazing fees or the terms of the permit can be expected to alter this *de facto* value that accrues to holders of Federal grazing permits.

The second implicit value of Federal grazing permits involves fluctuations in base ranch values due to changes in the grazing program or the specific grazing permit. According to the *Rangeland Reform Draft EIS* (U.S. Department of Interior 1994a), because permit values are associated with the privilege (not a right) to graze on Federal lands, permit changes that result in a reduction in base ranch value are not compensable. A change in base ranch value may show up as a change in market value if sold, or in the amount that a bank will loan to an operation.

Setting grazing fees for FS- and BLM-administered lands below commercial values is controversial. In 1989, BLM charged its operators $1.81 per AUM; comparable commercial values for forage were $8.49 per AUM (GAO 1990, cited in Cubbage and others 1993). Supporters of the current fee structure note that Federal grazing allotments typically require the permittee to install and maintain fencing and develop water for the livestock, whereas other land owners may include these items in their higher fees. The House report (U.S. House Committee on Natural Resources 1994) asserted that grazing fees are too low, not just by comparison with private grazing permits, but because they increase base ranch values and some can be subleased at a profit.

Half of the value of fees paid to the BLM by grazing permittees go into a Range Betterment Fund. The House report (U.S. House Committee on Natural Resources 1994) concluded that the grazing permittees appear to receive the benefits of most of the fees paid into this fund. Further, both the FS and BLM pay a portion of the grazing receipts to the states, which reallocate the money to counties. The House report (U.S. House Committee on Natural Resources 1994) questions the propriety of channeling these funds back into local grazing advisory boards controlled by ranchers.

The costs associated with managing public rangelands are another perennial issue. *The Rangeland Reform Draft EIS* (U.S. Department of Interior 1994a) tallies national data for BLM and FS rangeland management and rangeland improvement costs for 1993. Nongrazing expenses were costs associated with activities that preserved rangeland, such as monitoring rangeland condition and preventing trespass. All other expenses in the rangeland program were used for managing

Table 6.19—Program costs of managing public rangeland, 1993.

Category	Livestock grazing expenses		Nongrazing expenses[1]	Rangeland program costs	
	Total (Thousand Dollars)	Cost per AUM (Dollars)	Total (Thousand Dollars)	Total (Thousand Dollars)	Cost per AUM (Dollars)
Rangeland management	52,683	3.23	24,362	77,045	4.72
Rangeland improvements	12,456	0.76	4,535	16,991	1.04
Totals	65,139	3.99	28,897	94,036	5.76

[1] Nongrazing expenses are for activities that preserve rangeland, such as monitoring rangeland condition and preventing trespass. All other expenses in the rangeland program are for managing livestock grazing.

livestock grazing (table 6.19). The EIS (U.S. Department of Interior 1994a) reported that the BLM and the FS spent an average of $3.99 per animal unit month (AUM) of forage grazed by livestock on lands they administered; and that in 1993, the grazing fee was $1.86 per AUM.

Projections of Livestock Production

As part of the 1989 Resources Planning Act (RPA) process, the FS projected that national livestock production would increase steadily from 1986 to 2040, but that grazing supplied by permits on public lands would increase by less than 1 percent (Joyce 1989). On a national level, during the same time period, cattle herd inventories were expected to increase by 56 percent between 1986 and 2040, to approximately 55 million animals. Breeding ewe inventories were projected to more than double to 18 million. These projected increases were driven by an increasing domestic population, and to a limited extent, by increasing per capita consumption and international trade. Most of the increased demand for cattle and sheep was expected to be met on private lands. AUMs from FS lands were projected to increase over the period in FS Region 1 by 3 percent, have no change in Region 4, and decrease in Region 6 by 1 percent. BLM AUMs were projected to stay at current levels.

Different projections were made in the *Rangeland Reform '94 Draft Environmental Impact Statement* (U.S. Department of Interior 1994a). It found that historically, forage consumption by livestock has been decreasing on both BLM- and FS-administered rangelands in response to agency decisions about carrying capacity and resource protection and to operator decisions for business or personal reasons. These decreases of 6 percent per decade (BLM) and 8 percent per decade (FS) were projected to continue regardless of changes in the Federal grazing programs. Under the *Rangeland Reform '94 Draft EIS* (U.S. Department of Interior 1994a) "No Action Alternative," representing continuation of current management practices, decreases of 18 percent in livestock forage authorized by the BLM and 19 percent by the FS were projected over the 20-year analysis period. Factors contributing to the anticipated declines included stocking rate reductions from recognition of continuing resource damage and a declining economic feasibility of livestock grazing, as well as from implementation of recovery plans for Federally-listed threatened and endangered species. Under the *Rangeland Reform '94 Draft EIS* "Proposed Action" (U.S. Department of Interior 1994a), decreases in AUMs authorized are projected to be slightly greater over the next 20 years: 20 and 21 percent below current authorizations for the BLM and FS, respectively.

Recreation[22]

In this section we discuss the rapid rise in demand for recreation in the Basin since World War II and the amount of recreation occurring on BLM and FS lands in the Basin today. To understand distribution of benefits from these lands we discuss characteristics of the people who recreate in the Basin. The total public supply of recreational settings is also characterized, and the portion of those settings managed by the FS and BLM is noted. We use willingness-to-pay concepts to assess the recreation value of all public lands and the part contributed by these two agencies. The roles of recreation in regional economies and agency budgets are also discussed. Finally, we describe an approach for predicting trends in recreation activity and ways in which management can affect both the quantity and quality of recreation.

Publicly owned lands[23] in the Basin provide significant recreation benefits to people living there, other residents of the seven states of the Northwest (the "greater Northwest"),[24] residents of the other 43 states, and citizens from other countries. Over 200 million recreation activity days per year were made to Federal lands in the Basin between 1991 and 1993, representing a minimum of $1.2 billion in willingness-to-pay benefits and supporting 220,000 jobs. Fishing provides the greatest willingness-to-pay benefits of any recreation activity ($293 million), followed by day use[25] activities ($251 million), winter sports ($230 million) and hunting ($146 million). Hunting, motor viewing, and day use activities support the greatest number of jobs (49,000; 40,000; and 34,000, respectively).

Historical Trends in Recreation

After the advent of transcontinental railroads, accounts of remarkable recreational fishing in the streams and lakes of the Basin attracted travelers (Craig and Hacker 1940). In the early twentieth century, recreational use of public lands in the Basin was limited by distance from population centers; railroads brought some visitors but access to the core of the forest reserves was inhibited by lack of trails. The Agricultural Appropriations Act of 1915 was the first significant Congressional recognition of recreation as a legitimate use of the national forests (Cubbage and others 1993). Visitation to Federal lands increased rapidly through the 1920s with the advent of the automobile.

Since World War II, there has been a steady increase in recreation activity in the West and the Basin, spurred by Depression-era public works development of trails and landmark lodges. Between 1945 and the early 1970s, recreation activity on public lands grew more than 10 percent per year driven by rapid population growth, increased affluence, improvements in cars and interstate highways, decreased gasoline prices, increased air travel, and the decline of the average workweek to 40 hours and 5 days (Walsh 1986). Land management agencies responded to this increase in recreation activity by developing resource and visitor management programs.

In the 1980s major changes occurred in the national recreation scene. Participation in many activities outpaced the projections in the report by the U.S. Outdoor Recreation Resources Review Commission (1962), largely because population grew faster than expected but also because technology spawned new activities (mountain biking, wind surfing, jet skiing) and made camping more feasible (Cordell and others 1990). Since 1980, recreation visitor days on FS-administered lands in the Basin have increased 2.3 percent per year; at

[22] This section was written by Amy L. Horne, based in part on a 1995 background report by Amy Molitor and Natalie Bolon. On file with: U.S. Department of Agriculture, Forest Service; U.S. Department of Interior, Bureau of Land Management; Interior Columbia Basin Ecosystem Management Project, 112 E. Poplar, Walla Walla, WA 99362.

[23] This assessment is only of recreation occurring on publicly owned lands because of the difficulty of surveying activity on private lands. Given the incomplete survey the estimates of recreation value and activity in the assessment area are understated.

[24] The "greater Northwest" is defined as those parts of Idaho, Montana, Oregon, Utah, Washington, and Wyoming lying outside the Basin plus Elko and Humboldt Counties, Nevada.

[25] Day use activities are defined as picnicking, family gatherings, swimming, collecting berries and firewood, and visiting interpretive centers, museums, historic or prehistoric sites.

these growth rates recreation use will double every 31 years. Visitation to National Park lands in the study area has increased 4.3 percent annually since 1984.

Wilderness designation, accelerated by the 1964 passage of the Wilderness Act, is one indication that society wants management of certain lands to be different than that of others. There is a range of opinions on how much wilderness is enough, depending on whether one regards public land wilderness as "locked up resources" or as "the last refuges." Oregon, Washington, Idaho, and Montana have each had a portion of their national forests designated as wilderness. A second round of wilderness designation has succeeded in Washington and Oregon, but attempts to designate more wilderness in Idaho and Montana have been stalled in Congress for the past decade.

Competing uses for Federal resources have caused disagreements over stewardship. The FS and BLM increasingly mediate conflicts among recreation users (for example, rafters versus jet boaters, snowmobilers versus cross-country skiers), and between recreationists and resource extractors. Increases in the recreational collection of nontimber forest products, such as mushrooms and huckleberries, and non-consumptive uses such as bird-watching further complicate the stewardship task of balancing competing demands.

Amount of Recreation Activity

Over 200 million recreation activity days per year were made to Federal lands in the Basin for selected activities (table 6.20). Day use and motor viewing[26] account for 45 percent of the recreation activity days occurring in the Basin. Camping (25 million activity days), fishing (18 million), trail use,[27] and hunting (16 million each) are the next most popular recreation activities in the Basin. One quarter of this activity occurs in the Central Idaho Mountain ERU; other ERUs in which significant recreation activity occurs include the Northern Glaciated Mountains, Lower Clark Fork, Northern Cascades, Southern Cascades, and Blue Mountains.

Who Participates in Recreation

The Basin is an important vacation spot for people from different parts of the country.[28] We used lifestyle data (Claritas 1994) that match or can serve as proxies for the 12 classes of recreation activities that occur on publicly owned lands: sightseeing is a proxy for motor-viewing, birdwatching is a proxy for wildlife viewing, hiking and horseback riding are part of trail use, downhill and cross-country skiing are included in winter sports. We divided the data into three spatial units: (1) the Basin, defined by the nine BEA regions, (2) the greater Northwest, defined as people living outside the Basin but in the seven Northwest states, and (3) U.S. residents living outside the greater Northwest.

In 1993, 149,024 people living in the Basin took vacation trips of more than one day's duration in Idaho, Montana, Oregon, Washington, or Wyoming (Claritas 1994). For people living in the greater Northwest, 410,548 per year took a vacation in these five states. Over 6.5 million people living outside the greater Northwest took vacations in this five-state region. While these numbers pertain to whole states and not solely to the Basin, they do reflect the demand for vacations in the region by people living in different parts of the country.

People living in the nine BEA regions are more likely to participate in certain recreational activities than the U.S. population (table 6.21). For freshwater fishing, for example, a higher percentage of people living in the Basin participate than the U.S. average (18.57% versus 15.17%); the

[26] Motor viewing includes sightseeing from automobiles and pleasure driving.

[27] Trail use includes biking, day hiking, horseback riding, backpacking, and walking.

[28] To examine the question of who participates in recreation in the Basin we used a marketing database (Claritas Corporation 1994) that estimates the number of adults in each census tract likely to participate in a given activity based on census data, purchasing information, and surveys.

Table 6.20—Recreation activity days in the Basin, by activity and Ecological Reporting Unit (ERU 1-13), averaged 1991-1993.

Source: Claritas Corporation (1994).

higher participation for this sport is particularly significant given its universal popularity. Driving all-terrain vehicles, birdwatching, horseback riding, hunting with a shotgun, motorboating, and snowmobiling are all activities residents of the Basin and the greater Northwest are more likely to enjoy than the average U.S. citizen. Backpacking, cross-country skiing, and hunting with a rifle are more popular in most parts of the Basin than in the United States. Greater differences in participation rates exist between people who live in rural areas and those in urban areas, inside or outside of the Basin, than income levels or occupations; this is particularly true for freshwater fishing in which participation rates among rural residents are 10 percent higher than those in urban areas (Claritas 1994). Income level makes virtually no difference in whether someone participates in fishing. Farmers, blue-collar workers, professionals and managers all have similar rates of participation in fishing.

Supply of Recreational Settings

The western United States offers greater recreational opportunities than the eastern United States for certain types of settings, especially those in remote, wilderness, or backcountry areas (Cordell and others 1990). Land-based opportunities are 5 to 15 times greater in the West than in the East; FS and BLM lands provide most of the remote backcountry settings. At the national level, opportunities for remote backcountry and roaded natural settings have been decreasing at 0.9 percent and 0.7 percent per year respectively, while developed recreational opportunities have been increasing 0.6 percent per year. Seventy percent of the unroaded areas of 200,000 acres or greater in the United States (except Alaska) lie in the Basin (fig. 6.17).

The supply of recreational opportunities on Federal lands can be described by the number of acres of various "Recreational Opportunity Spectrum" (ROS) classes. We use three classes: primitive/semi-primitive, roaded natural, and rural/urban. "Primitive/semi-primitive" lands are natural-appearing, of moderate to large size, and have road densities less than 1.7 miles per square mile. "Roaded natural" areas have moderate evidence of human activity that is generally in harmony with the natural environment and have higher road densities between 1.7 and 4.6 miles per square mile. "Rural/urban" settings are substantially modified from the natural environment, with a moderate to high density of visitors, and road densities greater than 4.6 miles per square mile. In the Basin, many of the Federal acres in this category are ski areas.

About 60 percent of the Federal lands in the Basin fall into the roaded natural category; 40 percent are primitive/semi-primitive and less than 1 percent is rural/urban. The FS and BLM manage over 90 percent of the Federal acres available for recreation in almost every ERU and ROS class in the Basin (table 6.22). Almost one-third of the primitive/semi-primitive ROS acres lie in the Central Idaho Mountains ERU; other ERUs with substantial amounts of this ROS class include Northern Glaciated Mountains, Owyhee Uplands, Blue Mountains, and Snake Headwaters. The Southern Cascades and Upper Klamath ERUs

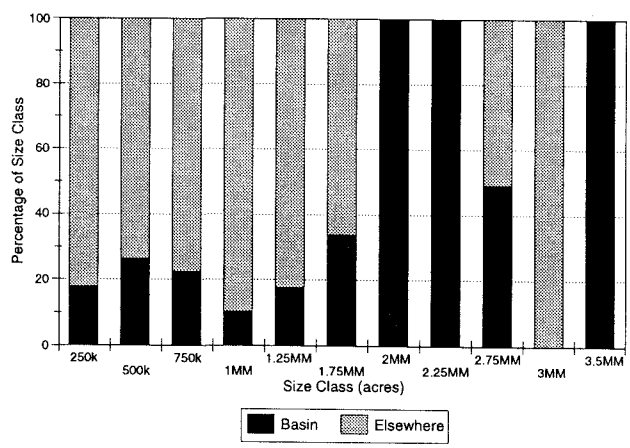

Figure 6.17— Contribution of large unroaded areas in the Basin to supply in contiguous United States, by size of unroaded area.

Table 6.22—Supply of recreational opportunities on Federal land in the Basin; acres and percentage managed by Bureau of Land Management (BLM) and Forest Service (FS), overall and within each Basin Ecological Reporting Unit (ERU) by combined Recreation Opportunity Spectrum (ROS) class, 1995.

Ecological Reporting Unit (#)	ROS combined class					
	Primitive/Semi-primitive		Roaded natural		Rural/urban	
	Acres	Percent	Acres	Percent	Acres	Percent
Northern Cascades (1)	2,073,679	91.26	1,551,382	95.71	58,812	99.89

Upper Klamath (3)	215,750	93.15	1,750,932	90.30	1,917	73.66
Northern Great Basin (4)	2,015,596	99.06	5,538,392	99.71	17,694	96.78
Columbia Plateau (5)	948,459	66.54	2,498,284	91.51	43,720	9.72
Blue Mountains (6)	2,468,990	99.58	4,001,988	99.70	8,329	92.71
Northern Glaciated Mountains (7)	3,880,995	77.00	3,908,036	93.19	13,066	96.48
Lower Clark Fork (8)	1,336,008	98.62	2,978,974	100.00	10,953	100.00
Upper Clark Fork (9)	1,410,313	100.00	1,615,809	99.73	6,561	100.00
Owyhee Uplands (10)	3,247,570	98.12	7,925,540	98.31	17,523	92.52
Upper Snake (11)	892,485	93.01	2,413,857	97.96	1,617	78.67
Snake Headwaters (12)	2,277,987	97.86	1,722,256	98.97	1,915	66.74
Central Idaho Mountains (13)	9,086,858	97.09	7,524,897	99.94	9,265	96.47
Total	30,279,474	93.79	44,972,809	97.84	193,230	77.08

have few primitive/semi-primitive recreation settings, especially given their proximity to population centers. In the roaded natural ROS settings, Owyhee Uplands and Central Idaho Mountains each account for nearly 8 million acres; the Northern Great Basin, Blue Mountains, Northern Glaciated Mountains, and Lower Clark Fork also have significant amounts of roaded natural settings.

Roaded natural settings provide for 74 percent of all activity days. They offer over 68 percent of all activity days for all types of recreation except trail use and camping (table 6.23). Trail use occurs predominantly in primitive/semi-primitive areas (56%). About half of camping occurs in roaded natural areas, and 26 percent each occurs in primitive/semi-primitive or rural/urban. About 24 percent of winter sports occur in rural/urban settings.

Willingness-to-pay for Recreation on Public Lands in the Basin

Willingness-to-pay for recreation on Federal lands in the Basin is at least $1.2 billion per year. Values vary greatly between ERUs reflecting in part the unique set of recreation advantages offered by each. For example, the Central Idaho Mountain ERU accounts for nearly one-quarter of all recreational benefits from Federal lands in the Basin (table 6.24). Other ERUs with high recreational values include the Northern Glaciated Mountains, the Southern Cascades, the Blue Mountains, and the Lower Clark Fork. Differences between regions reflect differences in numbers of visits, the types of activities occurring in them, and willingness-to-pay associated with each activity.

Table 6.23—Distribution of recreation activities in the Basin between Recreation Opportunity Spectrum (ROS) classes, 1995.

Activity	ROS Class		
	Primitive/Semi-primitive	Roaded natural	Rural/urban
	Percent		
Camping	26.10	48.13	25.77
Day use	10.19	73.81	16.00
Fishing	13.84	80.93	5.22
Hunting	21.88	75.19	2.93
Motor boating	14.23	70.08	15.69
Motor viewing	6.27	87.48	6.25
Nonmotor boating	7.84	84.86	7.30
Off-road vechicles	20.03	75.46	4.51
Snowmobiling	14.55	81.19	4.26
Trail use	56.12	36.64	7.24
Viewing wildlife	13.85	78.30	7.85
Winter sports	8.05	67.87	24.08
Total Recreation Activities	13.67	74.10	12.23

Note: Percents may not add to 100 due to rounding.

To some extent these differences are distorted by differences in size. Some ERUs have high value by virtue of being large. This makes the high values of the smaller ERUs, for example Southern Cascades and Lower Clark Fork, more striking. Lands administered by the FS and BLM provided $1.0 billion (83%) of the recreation benefits in the Basin (table 6.24). These data probably underestimate total value (and overestimate the percent contribution of FS and BLM lands) because only 77 percent of the surveyed management units provided usable data, and no activity occurring on private land is included. The values of the Snake Headwaters and Columbia Plateau ERUs are understated because of missing data from the Army Corps of Engineers and Yellowstone and Grand Teton National Parks.

Fluharty (1995) found the value of recreational fishing supported by salmon spawned and reared in the Basin to be about $9.7 million per year (1987-1991). Fish caught in the Columbia River represent 81 percent of this value and the rest were caught in the ocean off Alaska, Canada, Washington, Oregon and California. Three-quarters of this value ($7.3 million) is contributed by recreational steelhead fishing in the Columbia River. Most of the rest of the value lies in the recreational fishing for fall chinook caught outside the Basin.

Solely within the Basin, fishing is the recreational activity providing the greatest willingness-to-pay benefits, nearly $300 million (table 6.25). Day use is another highly valued activity ($250 million per year), about half of which occurs on FS- and BLM-administered lands. Winter sports like downhill and cross-country skiing also provide

Table 6.24—Average annual willingness-to-pay for recreation in the Basin, by Basin Ecological Reporting Unit (ERU) and Recreation Opportunity Spectrum (ROS) class, for all Federal lands and Forest Service- and Bureau of Land Management-administered lands (FS-BLM), 1991-1993.

substantial benefits ($230 million per year), and take place predominantly on FS- and BLM-administered lands. Hunting ($146 million/year) and camping ($75 million/year) are other high value activities. Snowmobiling and off-road vehicle (ORV) use are lower value activities because of lower participation rates, but the FS- and BLM-administered lands provide almost all the suitable settings.

Our assumption that each ERU has unique recreation value is borne out when we calculate recreation value per unit land area (table 6.26). Current value reflects aspects of both recreation supply and demand: the natural character of the area, road networks, wilderness allocation, distance from population centers, and the age and income characteristics of those populations. The ERUs that currently have highest recreation value are the Southern Cascades, Lower Clark Fork, Central Idaho Mountains, Northern Cascades, and Upper Clark Fork. Each ERU has a unique mix and relative value of recreation activities. Some ecological units show distinct advantages in providing certain recreation activities; for example, the Southern Cascades and Central Idaho Mountains are highly valued areas for fishing.

Contribution of Recreation to Regional Economies

In Idaho, Oregon, and Washington, tourism is one of the three most important generators of outside income (Nolan 1993). In the past few years, Montana's economy has been driven largely by an influx of new residents and the strength of the tourism sector (Sommers and others 1995). Montana's wildlands play an important role in its

tourism sector. Although only about one-quarter of non-resident visitors engaged in wildland-based activities, they accounted for half of the economic impact associated with non-resident travel in Montana (Moisey and Yuan 1992).

We calculated jobs associated with recreation activity by multiplying the number of recreation activity days by the response coefficients (listed in appendix 6-B) for residents under the column for "jobs, direct effects."[30] Throughout the Basin, recreation supports nearly 220,000 jobs. The percentage of the job force supported by recreation is above that of the Basin in the Idaho Falls, Missoula, and Redmond-Bend BEA regions (table 6.27). In the Pendleton BEA region, another area with high recreation use, the percentage of jobs supported by recreation is equal to that of the Basin; the lower levels of day use and motor viewing reduce the importance of recreation in Pendleton relative to Redmond-Bend. Other BEA regions have higher than average recreation jobs focused around specific activities; fishing, motor boating, and winter sports contribute to jobs in the Boise region; hunting, snowmobiling and viewing wildlife are significant to the Butte region. While significant numbers of jobs are supported by recreation in the Spokane and Tri-Cities BEA areas (34,608 and 18,640 respectively), the economies are so large that recreation jobs do not form part of the base.

Fluharty (1995) found that:

> *In the Basin much of the recreational [fishing] activity takes place on public lands and waters. Free access for fishing tends to equate with low value to users and land managers alike, however, access is only one part of the equation. Purchases of food, equipment, lodging, transportation, licenses and other accouterments of recreational fishing add up to significant expenditures. In some areas, whole towns, resorts, businesses and individuals are highly dependent on sale of services to people who participate in recreational fishing.... The economic values of recreational fishing are significant, diverse, and pervasive in the Basin.*

He estimates that 56 percent of these fishing expenditures occur in eastern Washington, 20 percent each in Idaho and eastern Oregon, and 4 percent in Montana. The Basin portions of each state attract fishing enthusiasts from other parts of the same state. Within the Basin about 70 percent of the fishing activity is generated by residents and 30 percent by non-residents. Great variation in attraction to non-residents exists across the Basin, however, with fishing participation in eastern Washington being only 8 percent non-resident while in Montana non-resident participation is 52 percent.

Fish viewing, part of wildlife viewing, results in $80 million per year in expenditures (Fluharty 1995). This activity includes viewing salmon spawning in rivers and streams, viewing stations at dams and fish ladders (these account for millions of visits per year), fish hatcheries, and fish festivals.

Recreation in Agency Budgets

The fees collected by state and Federal agencies from recreational visitors are much less than either agency costs or benefits provided. Low recreation fees are the result of policy decisions and legal restrictions. In addition, revenues from special use permits are only 1 percent of the net economic benefit provided by Federal lands in the Basin ($12.8 million collected in 1993) (table 6.28). This policy decision underprices recreation experiences on public land, resulting in agency revenues hardly covering the costs of roads, trails, facilities, maintenance, and education. One argument for this policy is equity; it enables all Americans to recreate on Federal lands regardless of their wealth. However, a consequence is that people treat recreational settings as a common good, causing the classic tragedy of over-use. (There are cases,

[30] The recreation response coefficients were calculated by Greg Alward, U.S. Department of Agriculture, Forest Service, Rocky Mountain Research Station, Land Management Planning, Fort Collins, CO.

Table 6.27—Percentage of employment supported by recreation activities for the Basin and Basin Bureau of Economic Analysis (BEA) regions, 1991-1993.

Oregon Parks and Recreation	1,953,933
Idaho State Agencies	2,700,905
Total	12,768,792

however, where permit systems are implemented to avoid over-use.) Also the lack of recreation fees, equivalent to prices, means that the agencies do not receive revenues that reflect the value of the recreation opportunities they provide, and hence have little incentive to provide them. Further, low rate schedules have been criticized for being inconsistent between agencies and for giving special advantages to large concessionaires (U.S. House Committee on Natural Resources 1994).

Predicting Recreation Trends

Population growth and the proportion of that population having a degree of affluence are the most significant factors contributing to increases in recreation activity (English and others 1993). The significant population increases expected for the Basin, the greater Northwest, and the rest of the United States over the next 50 years indicate major increases in recreation activity on FS- and BLM-administered lands in the Basin. These factors plus the percentage of people in the age range in which they are most likely to engage in physically demanding recreation activities, the price of recreation, availability of suitable recreational opportunities, as well as opportunities for substitute activities, capture most of what determines recreation demand.

We estimate future recreation demand using population projections for each county in the seven states in which the Basin is located. Number of people, population age structure, and income level are characteristics used to predict the number of trips for each activity. Regression coefficients are taken from the RPA and modified by regionally specific data (English and others 1993, Hospodarsky 1987, Hospodarsky and Lee 1989).

Age structure influences recreation activity because older people tend to travel further for recreation, stay in developed campgrounds, and stay longer than younger people (Cordell and others 1990). Younger people (age 18-34) are more likely to undertake more physically demanding activities such as skiing, backpacking, and mountain biking. Age, however, has little influence on participation rates in the more popular activities such as fishing, motor viewing, viewing wildlife, or picnicking.

We assume here that age will have the same effect on recreation activity in the future as it has in the past, but evidence exists that age-related participation rates can rise. Today older people have higher participation rates in more physically demanding sports such as downhill skiing, camping, hiking and backpacking than people the same age did 40 years ago (English and Cordell 1985). College education is also correlated with higher participation rates in active recreation, and the proportion of college-educated people in the population is increasing (Marcin 1993). This means that older age groups will tend to be more educated than people in those age groups today, suggesting their participation rates in active recreation will be higher.

Other studies have found differences in recreation participation by racial and ethnic groups and urban or rural residence (Dwyer 1994). These factors may shift recreation preferences somewhat; racial and ethnic groups are a small but growing proportion of the population and the U.S. population is expected to become more urban over the next 50 years. These factors are not included in the demand model because we do not know how differences in preference translate into numbers of trips for recreational activities. This omission probably makes little difference because percentage changes in racial and ethnic groups are expected to be small relative to total population.

In our treatment, the primary factor affecting supply of recreational opportunities is the number of acres in the three Recreation Opportunity Spectrum (ROS) classes. These were determined using output from CRBSUM regarding road density and vegetation pattern class. We assumed no change in ROS classification for lands in the Basin not administered by the FS or BLM, nor for any recreation locations lying outside the study area. The effect of changes in ROS supply is weighted by distance from population centers: thus changes in ROS acres on the Mt. Hood

National Forest (close to the Portland metropolitan area) will affect recreation activity more heavily than changes on the BLM Vale District. The model solves for demand and supply simultaneously and can be used to predict changes in visitation resulting from different scenarios or alternatives.

Other factors may also affect the quality and quantity of recreation activities in the Basin. Crowds of people may be the most significant factor limiting participation (Crocker 1985). Disturbances caused by insects, diseases, and fires also reduce recreation benefits in proportion with the severity of the disturbance; recreation value recovers as the forest recovers (Flowers and others 1985, Leuschner and Young 1978). Insect outbreaks have mixed effects on activities associated with fish and wildlife. Some fish and wildlife populations may be enhanced by increased dead wood in streams and forest stands, more vertical stratification, and more insect availability; some populations may be harmed by loss of cover, increased stream temperatures, and increased fire hazard (Gottschalk 1990).

Forest management activities can either enhance or detract from the quality of recreational experiences. Positive effects result from management that encourages diverse plant communities and stands having greater average tree diameters and higher trees per acre (Shaw 1977). Negative effects result from residual stands having low tree densities or small tree diameters (Walsh and others 1988). Management that degrades scenic quality or reduces the abundance and catchability of fish diminishes recreation benefits (Hueth and others 1988). Those silvicultural practices having positive, or avoiding negative, effects on recreation value are more likely to gain public approval of agency management activities than are others.

The issue of roads is complex. Roads can provide access for certain popular recreation activities but can permanently reduce wild, backcountry areas. Roads can reduce fish populations and catch rates, that affect the value of that site as a tribal or sport fishery. For example, erosion following logging and road building on the Salmon River caused the capitalized value of the fishery to drop from over $200 million to $14 million (Hueth and others 1988, Rice 1989). Roadless areas have recreation value in their own right; residents of Colorado and Utah reported household willingness-to-pay for wilderness ranging from $52 per year for 2.7 million acres to $92 per year for 16.2 million acres (Vincent and others 1995). Hiking is more highly valued in unroaded areas, while cross-country skiing is valued more highly in roaded areas (Walsh and others 1984b).

The reaction of recreationists toward critical habitat designation depends on its extent and location. Since riparian zones tend to be more important for recreation than upland areas, critical habitat designation for salmon in the Basin may cause extensive, unmitigatable recreation losses especially to boaters and anglers (Haynes and others 1992). The closing of certain areas in Montana to protect bald eagle populations is viewed favorably, while closings to protect grizzly bears are not (Bradford 1994, Frost 1985, Vincent 1989).

Nationally, the greatest shortages in recreational opportunities are for primitive camping, backpacking, hiking, horseback riding, nature study, and wildlife observation (Cordell and others 1990). These are recreational settings for which the Basin public lands have a comparative advantage that, if maintained, will increase in value.

In the future, recreation demands for the public lands in the Basin will continue to increase. The Basin offers more recreational opportunities, especially in undeveloped and remote settings for land-, snow-, and water-based activities, than other regions in the country. The relative importance of recreation opportunities in the Basin will increase over time. As more people travel to the Basin for vacations, recreation will become an increasingly important export.

Special Forest and Range Products[30]

This section reviews the little information available about the special forest and range products industry in the Basin. It identifies the species of the greatest economic value, employment opportunities, and the future direction of the industry.

The collection of forest and range plants east of the Cascade crest for commercial processing and trade is a small but growing industry. Between 85 and 90 percent of the special forest and range products industry currently takes place west of the crest of the Cascade Range (westside), generating hundreds of millions of dollars in product sales (Schlosser and Blatner, in press). During the past few years the industry has been expanding from the west of the Cascade Range to that area east of the crest (eastside). However, it will take at least a decade before the industry in the Basin begins to approach the economic maturity seen in its westside counterpart. Historically, collection of wild products has decreased as techniques for cultivation or synthesis have been developed. This has been the case for the Pacific yew, because Taxol, a drug used in cancer treatment, can now be produced without yew bark.

The issue of tribal use should not be confused with this discussion; the entire dimension of tribal use of plants and animals is discussed in the Social Assessment chapter. Competition over many of the special forest and range products is a key issue for the tribes, particularly given the growing commercialization of many species in recent years.[31]

Economic information pertaining to the special forest and range products industry is difficult to obtain because data on jobs and harvest values are not regularly reported and many of the transactions are on an unrecorded cash basis. Most of the information available here has been provided by two surveys: a 1989 survey of the floral greens and Christmas-ornamentals processors on the westside (but not the eastside) of the Cascade crest, and a 1992 survey of wild edible mushroom processors in Washington, Oregon, and Idaho (Schlosser and Blatner, in press; Schlosser and others 1991).

Total sales of special forest and range products in the Pacific Northwest range between $172 and $180 million (table 6.29). About 85 percent of the total sales value is derived from products collected on the westside; four-fifths of the westside total sales is derived from sales of floral greens and Christmas ornamentals. Even though many of the same or similar plants grow on both sides of the Cascade Range, harvest on the eastside of the Cascades is minor compared to harvest on the westside. This difference is primarily due to the lack of harvesters and industry infrastructure. The wild, edible mushroom industry is probably the most valuable special forest and range product activity in the Basin. Harvesting and processing of huckleberries may generate as much as $10 million in annual sales. (In table 6.29, huckleberries are included in the category named "other edibles and medicinals.")

The number of people working in the special forest and range product industry in the Basin is unknown. There are probably thousands of mushroom harvesters and perhaps a similar number of harvesters of baby's breath and huckleberries. In 1992 some 1,500 people harvested Pacific yew, but these jobs are expected to disappear shortly.

In the special forest and range product industry as a whole, about 70 percent of the jobs involve harvesting. These are frequently low paying, seasonal jobs with no medical or retirement benefits. Something close to full-time employment can be had by shifting from product to product throughout the seasons. The number of jobs may be overestimated due to double-counting of people working on more than one special forest or range product (Schlosser and Blatner, in press).

[30] This section was written by Amy L. Horne based on a background report prepared by William E. Schlosser and Keith A. Blatner (in press). On file with: U.S. Department of Agriculture, Forest Service, Pacific Northwest Research Station, Portland, OR.

[31] Personal communication. 1995. R. Hanes, Bureau of Land Management, Portland, OR.

Table 6.29—Value of special forest and range products collected east and west of the Cascade crest in Oregon and Washington, 1989.

Item	East	West	Total
	Dollars		
Floral greens & Christmas ornamentals	7,425,000	121,075,000	128,500,000
Wild mushrooms	11,800,000	26,800,000	41,100,000
Other edibles and medicinals	NA	NA	2 -10 million
Total	greater than 19-29 million	greater than 148 million	greater than 172-180 million

NA = information not available.
Source: Schlosser and Blatner (1997).

Processing jobs, which account for 30 percent of employment in the special forest or range product industry, and marketing jobs are the best paying jobs in the industry. Most facilities that process special forest and range products for market are concentrated west of the Cascade Range and are larger and more established than processing facilities located in the Basin. They typically deal with more than one product line, switching throughout the year as resource supplies and product demands dictate.

Timber[32]

Timber supply and demand are determined by the simultaneous interaction of global, national, regional, and local consumers, producers, and landowners. The purpose of this section is to present one perspective of future timber supplies that accounts for the impacts of recent changes in the direction of forest management. This perspective is taken from the *1993 RPA Timber Assessment Update* (Haynes and others 1995).[33] There are four parts to this perspective: (1) a broad overview of prospective timber demands; (2) the associated trends in timber supplies; (3) an overview of past, present, and future forest products production, harvests, and stumpage prices in the Basin; and (4) a discussion of two general issues: the effects of increased salvage logging, and future employment prospects for the forest sector in the Basin.

Future trends in the timber market, like all projections, are dependent on the underlying assumptions. These assumptions include trends in broad economic indicators such as population, gross national product, disposable income, and per capita disposable income (see table 6.3). There are also specific assumptions about housing starts, timberland area, shifts in land management intensity and growth rates of various forest types, and broad assumptions about the role of technological advances in creating demand for new products and increasing labor productivity. (These and other assumptions are described in detail in Haynes 1990, Haynes and others 1995.) A notable assumption included in this discussion is the unexpected recent increase in the use of recycled fiber. In the late 1980s, projections were for recycling rates to increase 33 percent over the next 50 years; instead recycling rates increased 67 percent between 1989 and 1994 in response to forest products industry initiatives and waste management concerns and are now expected to improve by another 30 percent by the year 2040.

[32] This section was written by Richard W. Haynes.

[33] The FS is required by the Forest and Rangeland Renewable Resources Planning Act (RPA) of 1974 to prepare a renewable resource assessment. The purpose of this RPA assessment is to analyze the timber resource situation to provide indications of the future cost and availability of timber products to meet the Nation's demands. The analysis also identifies developing resource situations that may be judged desirable to change, and it identifies developing opportunities that may stimulate both private and public investments.

Prospective Timber Demands

Timber demands can be projected using expected trends in per capita consumption. Economic theories of natural resource use often assume that resource use increases as population and income grow (Cliff 1973). Facts point to a different reality. In spite of a steady increase in per capita income, per capita consumption of all forest products in the United States has varied over the past decades, from 80 cubic feet in 1950 to a low of 54.1 cubic feet in 1970, to a high of 82.8 cubic feet in 1986, back down to 74 cubic feet in 1991. Perhaps more important has been the change in the composition of product consumption. Per capita consumption of solid wood products has fallen, although in recent years it has rebounded as Americans have spent more to repair and alter existing housing units. Per capita fiber consumption has increased 45 percent over the past four decades with most of the growth taking place in the 1950s and 1960s. Finally, fuelwood consumption, which fell by 82 percent between 1950 and 1970, rose rapidly in the 1970s. By the late 1980s it had once again matched the 1950 level.

Recent research in the United States suggests that per capita wood product consumption will decline slightly over the next 50 years (Haynes 1990; Haynes and others 1995; U.S. Department of Agriculture, Forest Service 1988). This view of the future places less reliance on solid wood products manufactured from logs and greater reliance on engineered and reconstituted products for structural applications. It assumes a greater use of recycled fiber and greater demand for nontimber commodities and noncommodity benefits (such as some recreation activities) from forests. In spite of this, total roundwood consumption in the United States is expected to grow 0.7 percent per year to 26.5 billion cubic feet by the year 2040. This is about the same rate of change as expected for U.S. population growth.

The largest demand increases (in terms of roundwood) are for sawlogs and pulpwood. The faster growth in the demand for roundwood, in terms of percentage, is in miscellaneous products (including oriented strand board) and fuelwood. Softwood demand is primarily for sawlogs and pulpwood, but the largest parts of hardwood demand are for fuelwood and pulpwood, with hardwood sawlogs a close third.

Prospective Timber Supplies

In spite of increasing environmental regulations, timber harvests during the next 50 years are expected to grow from 18.1 to 25.3 billion board feet or 0.7 percent per year. Harvests will increase slightly faster than demand as U.S. production partially replaces imports of Canadian lumber and newsprint.

Softwood timber harvest has increased by more than 60 percent over the last four decades. It is projected to increase an additional 35 percent (0.6% per year) to 14.6 billion cubic feet by the year 2040. Slowing domestic demand, increased use of recycled fiber, and increasing use of hardwoods account for this slower projected growth in demand for softwood timber. The Pacific Northwest and the South are expected to remain the two most important timber producing regions in the United States.

Hardwood harvests have nearly doubled over the past four decades and are expected to increase at about 0.9 percent per year throughout the next 50 years. In the near term, increases are a function of substitution of hardwoods for softwoods in paper and paperboard production. The rapid increase in the use of recycled fiber in paper and paperboard production has been holding down the growth in harvests since 1988 and will continue to do so until the year 2000.

The proportion of softwood harvest coming from public timber lands peaked in the late 1960s at 30 percent of total softwood harvest. In 1991, harvests on public lands accounted for 23 percent of the total harvest: 17 percent from lands administered by the FS and 6 percent from an assortment of other federal, state and local agencies. Because harvesting on Federal lands declined in the early

1990s, the proportion of harvest occurring on public land is estimated to have been 17 percent in 1995. The reduction in Federal harvests has also decreased the percentage of the national timber harvest occurring in western states from 55 percent to 45 percent, while the percentage of the national timber harvest occurring in eastern states has increased from 45 percent to 55 percent.

Prospective Price Trends

Price trends for forest products differ sharply between the solid wood and paper sectors. For solid wood products such as softwood lumber, we expect real price increases to be roughly 0.7 percent per year. For paper and paperboard, the expected long-term trend is for no change in constant real prices. Both trends are consistent with past price behavior.

Real stumpage price inflation over the next two decades is expected to follow the long-term trend growth (2.5% per year). Stumpage prices are expected to increase in the next 15 years as the transition from harvesting natural stands to harvesting managed stands is completed and as harvests on public lands are reduced in the western United States. In the long term prices will stabilize, reflecting a balance between supply and demand in both the stumpage and wood product markets. Increasing use and availability of recycled fiber may restrict price increases in the 1990s. Pulpwood prices may also experience growth but only after the year 2010.

The Basin

Against this background of prospective national trends in the forest sector, timber harvest levels in the Basin have been declining since the early 1960s as a proportion of total U.S. harvest (table 6.30). Currently, they account for 10 percent of total U.S. harvest. Timber harvests in the Basin have declined by roughly 7 percent since 1986 and are expected to decline by another 7 percent by the end of the decade. Public harvests currently account for 46 percent of the total harvest and the forest industry ownership is larger than the other private ownership. Current projections for lumber and plywood production (table 6.30) between the years 1991 to 2000 are for a drop in lumber production of 800 million board feet and an increase in structural panel production of roughly 500 million square feet (Haynes and others 1995).

Stumpage price trends for the Eastside and UCRB EIS areas from 1943 to 1993 are shown in figure 6.18. Price volatility increased beginning in the 1970s because stumpage prices were being pushed up by increased competition among buyers, first in the lower Basin and then in the 1980s in the upper Basin. Stumpage prices are expected to increase in the near term as a consequence of cumulative Federal land management planning decisions and actions to protect the northern spotted owl, marbled murrelet, and anadromous fish species. Real (inflation-adjusted) stumpage prices in 1995 are on average 118 percent higher than 1989 levels in eastern Oregon and Washington. Over the next two to five decades prices are expected to stabilize, reflecting a balance between supply and demand in both the stumpage and wood product markets.

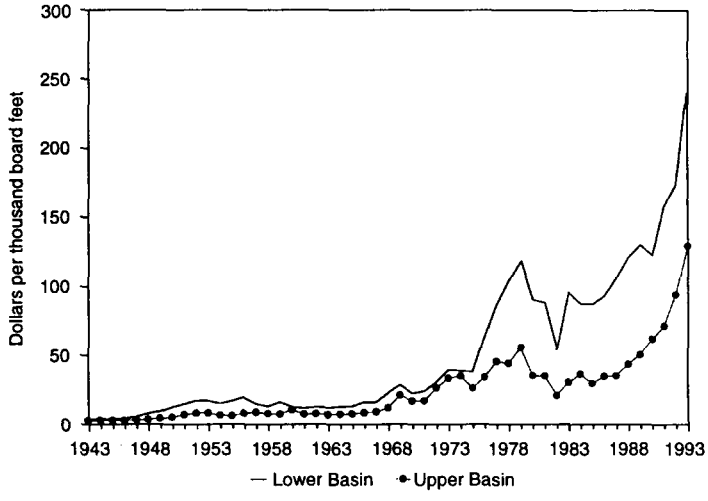

Figure 6.18— Average stumpage prices for National Forest timber, Lower (eastern Oregon and Washington) and Upper (UCRB) portions of the Basin assessment area, 1943-1993.

Table 6.30—Softwood harvest, stumpage prices (in constant 1982 dollars), and lumber and structural panel production in the United States, Eastside and UCRB areas,[1] by land ownership, to 2040.[2]

[3] NA means data is not available.

[4] UCRB refers to those portions of the project covered by the Upper Columbia River Basin EIS planning area, that is, northern Idaho, southern Idaho and western Montana.

In addition to describing the basic primary economic trends, we also need to describe the basic trend in employment in the forest sector [primarily the lumber and wood products industries, or Standard Industrial Classification (SIC) 24]. Past and projected direct employment in SIC 24 is shown in table 6.31. Broadly, the historical data for the lower Basin (eastern Oregon and eastern Washington) suggests that there is no trend in employment (expressed as jobs/million cubic feet) that might be attributed to improvements in technology such as those that occurred west of the Cascade Mountains. In the upper Basin (Idaho and western Montana), there has been a downward trend in jobs per million cubic feet.

During the next two decades we expect modest declines (around 10%) in SIC 24 employment because of continued harvest declines. In the longer term employment is expected to stabilize first and then increase, mirroring increases in harvest levels.

Timber Harvest Projections by BEA Regions

Disaggregating timber harvest into the nine BEA regions poses some difficulties because of the lack of specific county data for harvest by ownership. Recent harvest levels and projections are shown in table 6.32. Four BEA areas (Spokane, Missoula, Redmond-Bend, and Pendleton) account for more than 80 percent of the timber harvest in the Basin.

Timber harvest from lands managed by the FS (88% of total timber harvest from public lands) plays a different role in the forest products industry in different parts of the Basin. In eastern Oregon and Washington, FS timber represented 59 percent of total harvest in 1991; in the UCRB it represented 34 percent (table 6.30). This raises the question of whether the forest products industry is dependent on Federal timber and land management polices. The projections in table 6.30 show that a 50 percent decrease in Federal harvests will reduce lumber production in the Basin by 16 percent.

Numbers have been rounded.

Some of the reduced harvest is made up by increases from private timberlands, but private inventories are insufficient to completely offset declines in Federal harvest.

Under this assumption, total employment in the forest sector will decrease by 4,000 direct jobs in the 1990s (10%). This can be compared against overall job growth in the Basin over the same period, which is expected to be more than 265,000 jobs. It is likely there will be opportunities for people who lose jobs in the forestry sector to find employment in other industries.

Salvage Issues[34]

Recently, there has been much discussion about an increase in a salvage logging program (The Taylor Amendment) primarily in the inland West. Such a program has its scientific basis in the Eastside Forest Ecosystem Health Assessment (Everett and others 1994) which envisioned management prescriptions focusing on restoration of high hazard landscapes and aquatic ecosystems. The economic implications of an annual 2-billion-board feet salvage program (starting in 1995) were explored using the timber assessment market model (Adams and Haynes 1980), and are illustrated in table 6.33. Comparing tables 6.30 and 6.33 shows that such a salvage program has nearly instant effects in the Basin. Stumpage prices in the West, for example, drop by 9.8 percent in 1995 and 14.4 percent by the year 2000. Price reductions for softwood lumber are more modest, 2.4 percent per year by the year 2000.

Salvage of dead and dying trees presents several economic opportunities and concerns. These include product recovery, harvesting systems, roads, and desirable and undesirable effects on the residual trees and the rest of the forest ecosystem. Dead and dying timber in the Basin may be economically salvaged for chips, lumber, veneer, and composites. Standard issues in product potential are complicated for dead or dying trees by insect damage, checking, fungal stain, decay, and charring. Losses in both value and volume increase with the amount of time dead trees stay on site; the greatest loss is for uses in which wood appearance is important, such as for millwork or furniture stock. Potential value loss is highest for ponderosa pine because stain can rapidly reduce the value of select-grade lumber from $1,800 per thousand board feet (MBF) to $300 to $500 per MBF. Timber that has remained standing on site for two years also becomes brittle. This increases safety hazards for salvage operators and reduces value because it may result in non-standard log lengths.

Rate of deterioration in dead and dying trees is influenced by species, tree size, location, and timing. Thin bark species are more susceptible to fire and other mortality agents. Cubic volume losses range from 0 to 30 percent the first year depending on species and increase thereafter; the highest volume losses are in true firs, followed by Douglas fir, and then pines. Small trees deteriorate more quickly than large ones. Fungal growth is enhanced in locations in which trees have a moisture content between 15 percent and the fiber saturation point, and the temperatures lie between 41 and 95 degrees Fahrenheit. Checking of the bole is increased by drying winds, sunlight, and high temperatures. Timing of tree death is important relative to weathering agents and timing of insect population flight cycles and preparation of brood colonies.

Scale of salvage operations—If all of the vast amount of timber available for salvage in the Basin were to be harvested, large-scale operations may be required. This could deter use of lower impact harvesting methods (for example, horse logging) and foster a boom-bust dynamic counter to the interests of local community development. Salvage operations can have either positive or negative effects on the residual stand, depending on how they are conducted. Salvage is often promoted for restoration of drought- and disease-prone forests to more typical mixes of fire-tolerant species in the

[34] This section was partly based on a background report provided by S.A. Willits (1995).

[4] UCRB area refers to Upper Columbia River Basin EIS area.

Basin. Properly done, thinning can increase insect resistance of the residual stand by increasing its vigor. On the other hand, thinning also poses a risk of damaging advance regeneration and increases opportunity for insect and disease damage if physical damage to residual trees occurs.

The potential for use of trees salvaged in the Basin for roundstock (fence posts, marine pilings and utility poles) appears limited because the tree species, with the exception of ponderosa pine, are difficult to penetrate with preservatives and markets are distant from the resource. Decay that infects dead trees can continue to degrade the material even after harvest, making them unsuitable for use in log homes. Salvaged timber can be used for lumber, barring complications from breakage, stain, decay, and splits and checks. Decay can lower wood strength, causing problems in using salvaged timber for structural lumber.

Costs—Much of the implementation of ecosystem management will be through existing mechanisms for stand manipulations.[35] One challange will be to find inexpensive objectives. Field trials from eastern Oregon illustrate how a treatment of cattle grazing at the appropriate time and in the appropriate intensity for specific site conditions compared with no cattle grazing is an inexpensive way to reduce fine fuels, and to increase the production of stumpage biomass and stumpage value, while providing income from grazing early in the rotation (Weigand and others 1993). Grazing shifts biomass production away from shrubs and grasses to trees early in the rotation, and facilitates reforestation on dry sites. Emphasis on producing timber quality rather than timber quantity [such as Allowable Sale Quantity (ASQ)] may also produce greater revenue. Weigand and others (1993) found that when timely cattle grazing was combined with silvicultural treatments designed to maximize timber quantity, timber revenues increased 30 percent; when timber quality was emphasized rather than quantity, this combination created 70 percent higher revenues.

Harvesting methods that are consistent with goals for ecosystem management are likely to cost more than traditional methods. A study from the Lolo National Forest (Keegan and others 1993) compares the logging costs of different harvesting methods and increasingly complex stand retention patterns.

Silvicultural Treatment	Harvest method	
	Tractor	Cable
	..... Dollars per MBF	
Clearcut or Seed Tree	$87	$155
Shelterwood	$89	$164
Group Selection	$98	$219

Higher logging costs on national forests relative to private timberlands will lead to lower stumpage prices for national forest timber sales and result in lower payments to counties. On the other hand, such costs may be justified by the increased benefits of improved riparian ecosystem function, reduced fire potential, and increased recreational and scenic values.

The recent and anticipated increases in sawtimber stumpage prices (see figure 6.18) are also changing perceptions about which land management activities might be feasible in the Basin. These recent (real) price trends are consistent with past projections of rising prices for sawtimber and the roughly constant prices for roundwood material, as shown below:

[35] On public lands many of these costs are dispersed and hidden in existing funding mechanisms such as the timber program. For example, in 1992 only 56 percent of the amount funded for timber sales on the Wallowa-Whitman National Forest was for sale-related activities (McKetta and Weiner 1994).

Year	Stumpage price		Logging costs
	Sawtimber	Roundwood	
	..... Dollars per MBF		
1990	100	100	100
2000	189	82	110
2010	184	69	119
2020	208	73	129
2030	206	78	130
2040	212	86	146

The difference in price trends between sawtimber and roundwood reflect the ability of the pulp and paper industry to control the cost of roundwood because most of the supply goes to few buyers who can choose among many different fiber sources (especially the increased use of recycled fiber expected in the 1990s).

These forecasted stumpage prices have significant implications for the economic feasibility of harvesting the small-diameter, dense stands prevalent in some parts of the Basin. Using data provided by the Colville National Forest, we calculated the proportion at which net losses on harvesting chipwood (roundwood) are offset by net profit from harvesting small sawtimber to be 42 to 58 percent. Assuming current price projections and logging costs as shown in the last paragraph, the proportion will change to 59 to 41 percent by the year 2040. The implication is that stands consisting completely of roundwood-size timber (for chips) will not sell. In the future, as now, stands will have to contain some amount of sawtimber to be marketed. While that proportion is currently 58 percent, rising sawtimber prices will reduce it to approximately 41 percent by the year 2040.

Water[36]

Water use and water policies are not controlled by the FS and BLM, yet these agencies are, and will continue to be, affected by how others manage and use water in the Basin. This section examines emerging water allocation issues in the Basin and discusses how they may impact FS and BLM policies.

Western water laws developed in conjunction with hardrock mining laws because of miner's dependence on water to separate gold from gravel. Thus western water laws more closely resemble mineral law than water laws of the eastern United States, which require all landowners bordering a water course to share. Laws enable subsequent interests to withdraw water for legally-sanctioned, beneficial uses, such as mining, agriculture, industry, domestic and municipal supply, raising stock, or hydropower. But those preferring in-stream uses have had little legal recourse. An example of an in-stream use is the desire of American Indians to support fish populations. Historically, western water agencies granted all applications for water rights regardless of whether the water was already fully appropriated. Traditional water users thus have a vested property right to continue using water, making it difficult to reallocate water toward newly evolved and appreciated interests and uses.

Water Allocation and Demand in 1990[37]

Competing water demands in the Basin include withdrawals (for domestic, industrial, commercial, and agricultural uses), hydropower generation (which requires large instream flows to be economically feasible), aquatic habitat to support tribal, recreational, and commercial fishing, and other water-based recreational activities. The Pacific Northwest generates 40 to 50 percent of the Nation's hydroelectric power, mostly on the Columbia and Snake Rivers (Kale and Sifford 1993).

In the 93 counties included in the BEA regions, 34.3 billion gallons per day are withdrawn from both ground and surface water. Irrigated agriculture uses the greatest percentage of water in the

[36] This section was written by Amy L. Horne and Christopher Hanson.

[37] This analysis is based on 1990 data provided by the U.S. Geological Survey on water withdrawals in the 100 Basin counties for all uses.

Table 6.34—Water allocation in the Basin among domestic, industrial, commercial, livestock, and irrigation uses, by Basin Bureau of Economic Analysis (BEA) area, 1990.

BEA Area	Domestic, industrial, and commercial			Livestock use	Irrigation use	Total water use
	From public supply	From self-supply	Total			
	Million gallons per day					
Tri-Cities	408.91	118.14	529.05	12.68	5,295.31	5,835.04
Spokane	210.89	85.83	296.72	6.46	269.31	572.54
Missoula	36.72	47.99	84.71	3.41	920.97	1,009.09
Idaho Falls	58.82	176.38	235.20	7.98	7,801.22	8,044.40
Twin Falls	25.72	15.84	41.56	528.17	5,439.62	6,009.35
Boise	73.95	37.37	111.32	25.51	6,962.85	7,099.68
Pendleton	54.98	88.70	143.68	7.36	1,982.86	2,133.99

Basin (93%), with only minor amounts used for domestic, commercial, and industrial purposes (5%), and livestock (2%)(table 6.34). The Idaho Falls, Twin Falls, and Boise BEA regions account for 62 percent of the water withdrawals, 85 to 95 percent of which is used for irrigation. Irrigation generally uses water withdrawn from surface water, while public supply[38] usually withdraws from groundwater. Groundwater is withdrawn for irrigation in some counties in Idaho: Cassia [which withdrew 1,000 million gallons per day (MGD) in 1990], Minidoka (613 MGD), Bingham (1,200 million MGD), and Jefferson (700 MGD). The withdrawals for irrigation in these counties were substantially higher than the highest groundwater withdrawals for public supply in the Basin. For example, Spokane, Washington withdrew 117 MGD in 1990, followed by Ada, Idaho (37 MGD). Domestic per capita use throughout the Basin is between 120 and 170 gallons per day.

Most water withdrawals for irrigation are from surface water, effectively dewatering some rivers in summer months. The Boise, Idaho Falls, and Tri-Cities BEA regions each diverted over 4.5 billion gallons per day in 1990 while the Twin Falls BEA region diverted over 2.7 billion gallons per day.

Conveyance losses (water lost from irrigation systems and during field application) accounted for 50 to 65 percent of 1993 water use in the Basin.[39] However, some of this water returns to

[38] Public supply in this paper refers to domestic, commercial and industrial uses supplied by a municipal or state agency. In the data this is often referred to as "deliveries from the public supply" so that this water can be distinguished from self-supplied water.

[39] Personal communication. 1995. Brian Drost. Electronic data. U.S. Geological Survey, Seattle, WA.

aquifers or surface water sources and thus is available downstream. Conveyance losses that return to surface water as overland flow may transport nutrients and sediments. In several BEA regions, conveyance losses exceeded all consumptive uses combined (Idaho Falls, 2,700 MGDs; Boise, 3,000 MGD; Twin Falls, 1,700 MGD; and Missoula, 410 MGD).

Future effects of agriculture on water quality need to be recognized in developing strategies for conserving fish. In the United States, 57 percent of sediment discharged from non-Federal, rural lands comes from agricultural cropland. Erosion rates from croplands are five times those of forested landscapes (Brown and Binkley 1994). Sediment from cropland often transports nitrogen and phosphorous that facilitate eutrophication in reservoirs and algal growth in slow moving streams and rivers. It also can transport herbicides and pesticides that are absorbed into the food chain and accumulate in higher concentrations in the tissues of vertebrates such as fish.[40] A number of these agricultural impacts on water quality are described in the Aquatics Species and Habitats chapter.

Water use for agriculture and hydropower have mixed effects on recreational activities. Water withdrawals for irrigated agriculture reduce instream flows that may harm fish populations. The reductions in freshwater fishing that may result may negatively affect business activity driven by fishing. Opportunities for bird watching in the Basin, on the other hand, have improved because wetlands created by the dams have increased migratory waterfowl populations (Muckleston 1993).

[40] Of note is a recent report in *The Oregonian* about high concentrations of mercury found in the tissues of warm-water fish species in reservoirs in central Oregon. The mercury is said to have originated from run-off from long abandoned mines in the region.

Future Water Demand

The quantity of water used for irrigation is likely to become increasingly controversial as the human population continues to grow in the Basin, increasing municipal water demands (table 6.35). Recreational activity is also expected to increase with the population (McCool and Haynes 1996), some of which will increase pressures to maintain certain levels of water quality and in-stream water quantity.

The extent of the conflict over water use between municipalities and irrigators can be seen in projections based on per capita water use for commercial, domestic, and industrial water purposes, including both public and self-supply (table 6.35). Per capita use for each BEA region is largely a function of the amount of water used by commercial and industrial facilities. We assumed everyone will use public supply rather than private wells, so per capita use could be multiplied by the population projections to estimate future demands for public supply. The amount of water available for irrigation was estimated assuming constant rates of application per acre. By subtracting the municipal demand for the year 2040 from the 1990 total withdrawals, the reduction in irrigated acres was calculated for each BEA region. These numbers do not include demand for mining and power generation plants (other than hydropower).

Using these assumptions, eight out of nine BEA regions would have to reduce the amount of land in irrigated agriculture to meet municipal needs. The greatest impact would be in the Spokane BEA region which would have to reduce irrigated agriculture by 155,567 acres (11% of 1992 irrigated acres). Other affected regions would be Idaho Falls (81,531 fewer irrigated acres) and Redmond-Bend (53,443 fewer irrigated acres). The impact on the Pendleton BEA region would be about average for the Basin (35,824 fewer irrigated acres). The Butte BEA region would be one of the least affected (4,620 fewer irrigated acres). Any increases in the efficiencies of water distribution and use would lessen the number of acres affected.

Table 6.35—Projected water allocation in the year 2040 given expected population growth in the Basin, by Basin Bureau of Economic Analysis (BEA) area, 2040.

BEA Area	Municipal consumption per capita[1]	Irrigation use per acre	Total withdrawals[2]	Irrigation withdrawals	Population	Municipal water use[3]	Water available for irrigation[4]	Change in irrigation water[5]	Change in irrigation
	..... Gallons/day		.. Million gallons/day			..... Million gallons/day			.... Acres ....
Tri-Cities	422.10	3,364.02	5,835.04	5,295.31	1,402,569	592.02	5,243.02	-52.29	-15,545
Spokane	401.89	1,698.36	572.54	269.36	1,411,800	567.38	5.15	-264.21	-155,567
Missoula	390.62	3,780.04	1,009.09	920.97	468,197	182.89	826.20	-94.77	-25,070
Idaho Falls	843.90	5,775.22	8,044.40	7,801.22	846,120	714.04	7,330.36	-470.86	-81,531
Twin Falls	166.41	4,465.66	6,009.35	5,439.62	338,724	56.37	5,952.98	513.36	114,958
Boise	272.71	6,142.08	7,099.68	6,962.85	1,005,645	273.91	6,825.77	-137.08	-22,318
Pendleton	810.71	2,960.20	2,133.90	1,982.86	317,112	257.08	1,876.81	-106.04	-35,824
Redmond-Bend	811.59	3,910.15	3,016.94	2,822.19	497,444	403.72	2,613.22	-298.97	-53,443
Butte	278.05	3,907.60	616.56	585.32	177,279	49.29	567.27	-18.05	-4,620

[1] Assumes municipal demands supersede irrigation demand.

[2] Includes public plus self-supply for domestic, industrial, and commercial use.

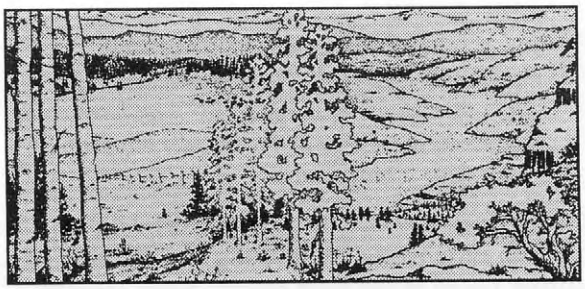
[3] Assumes constant per capita consumption.

[4] Assumes total withdrawals at 1990 rates and aquifers are not exhausted.

[5] Assumes constant water application per acre.

Only the Twin Falls BEA region would have surplus water and the possibility of increasing the number of irrigated acres, largely the result of the high number of domestic users on wells rather than public supply (25%) and low industrial and commercial use. As commercial facilities expand and municipal services improve, the per capita use in this region is likely to more closely resemble that of other regions (250 to 300 gallons per day).

In parts of the Basin where ground water withdrawal is very high, continuing the current rates of withdrawal may not be physically possible given the geographic extent and recharge rates of the region's aquifers. Non-domestic groundwater use may become controversial as the population grows.



It should be noted that the amount of irrigated acreage decreased ten percent during the agricultural recession of 1982 to 1992 (Jackson 1993). If this trend continues, municipal demands could be met if the current rate of withdrawals can be maintained. Another trend that may ease future conflicts over water allocations is the use of more efficient systems such as drip irrigation. An increase in drip irrigation may also reduce sedimentation associated with agriculture; however, poorly covered croplands will remain sources of sedimentation during heavy rainfall.

Change in water allocation is one of the options available for ensuring the viability of fish populations. Options to consider include conservation measures to guarantee in-stream flows in the long term and, hence, protection of crucial fish habitats. Such measures may result in the retirement of marginal cropland, but offsetting benefits may include higher instream flows for meeting future recreation and municipal demands.

ECONOMIC POLICY QUESTIONS

This section addresses four economic policy questions of interest to the BLM and the FS. They include the role of commodity production from public lands in providing community stability and the related issue of timber dependency, the role of the two agencies in future development of the regional economies in the Basin, the economic efficiency of public land stewardship, and the economic perspective on sustainability.

Community Stability and Timber Dependency[41]

The discussion of community stability and dependency deals mostly with timber and FS policy. This is because, despite recognition that communities may be dependent on other Federal resources (such as amenities, range, recreation, and water), the FS has implemented specific policy only with respect to timber. For the BLM, which predominantly manages rangeland in the Basin, the question of timber dependency is not as germane as for other agencies. Although there is a general sense that the Federal agencies have responsibility toward local economies in which they manage a lot of land, little is known about range dependence, or its specific dimensions in the Basin (other than what has been said previously in the "Range" section). The lessons from this discussion can be applied to the BLM and range-dependence, and other types of resource dependence by inference.

[41] This section was written by Richard W. Haynes, Amy L. Horne, and Nicholas E. Reyna.

This section first reviews the legal and political evolution of the FS's concept of community stability and the evidence about the extent of the agency's role. It then reviews the question of timber dependency and the process by which the FS defined timber-dependent communities. After evaluating this approach, we develop an improved method which identifies 29 communities in the Basin that may be sensitive to levels of public timber harvest. This approach does not address the dependency of the communities on other FS resources. This section ends with a discussion of the relationship between timber harvest and economic well-being.

Community Stability

The FS has no specific legal mandate to provide economic stability to rural communities; references in law and policy, however, permit and encourage consideration of economic stability when evaluating federal actions (Ashton and Pickens 1995). Dana and Fairfax (1980) summarize their concerns about FS policies on community stability as follows:

> *Mindful of the destructive boom-and-bust cycles which accompanied nineteenth-century forestry, the FS argued that the non-declining even-flow policy was necessary to assure community stability. Their analysis assumes, first, that stability is an accepted goal, as opposed to, for example, growth, diversification, or reorientation of a community's economic base; second, that the FS has a mandate and a capacity to*

contribute to that goal; and, third, that even flows of timber volumes from Federal lands contribute to that goal. None of these assumptions—the validity of the goal, the mandate, or the capacity to achieve it—is broadly accepted as a working assumption.

Initial concerns about the role of Federal timberlands in supporting community stability are usually traced to the early debates about creating forest reserves, first manifested in the Organic Administration Act of 1897 (Society of American Foresters 1989). The FS became an early proponent of promoting stability in forest communities through a sustained yield even-flow timber policy. The BLM received a legislative mandate in the Taylor Grazing Act (1934) to "stabilize the livestock industry dependent on the public range."

The National Forest Management Act (NFMA) of 1976 added to the community stability policy by solidifying a traditional but contentious strategy for timber flow from national forests through the sustained yield and nondeclining even-flow provisions (Section 11, 36 CFR 219.16). Both of these provisions were designed, in part, to address community stability issues (Dana and Fairfax 1980). NFMA also required bidding methods for timber sales to "consider the economic stability of communities whose economies are dependent on such national forest materials." Subsequent regulations required "dependent communities" to be one of several factors considered.

Wilkinson and Anderson (1987) argue that considerations of community stability and nondeclining even-flow are among the most ambiguous aspects of the NFMA's legislative history. This requirement traditionally has been interpreted as evaluating land management alternatives according to their impact on local jobs and income despite absence of any proof of a link between sustained yield of timber and community stability (Schallau and Alston 1987). Maintaining community stability through timber harvest and grazing policies more accurately reflects a political, not economic, choice that may be appropriate when it conforms to societal preferences regarding distribution of wealth. Recent recognition that FS and BLM policies play only a minor role in determining community stability has shifted emphasis toward policies that do not destabilize communities through abrupt increases or decreases in resource use (Forest Ecosystem Management Assessment Team 1993).

The FS took up the cause of stabilizing the economies of rural communities in and around Federal lands primarily through even-flow timber supply policies. Boyd and Hyde (1989) note that "community stability is the FS expression for its objective to maintain the integrity of those small communities scattered throughout the West that are dependent on public timber harvests." They found the agency policy "consistent with aggregate public policies designed to minimize the social costs of a cyclic economy." While resource-based communities have been at the mercy of larger macroeconomic forces, Boyd and Hyde (1989) found that translating this concern into a remedy was more difficult. The literature is ambiguous, at best, regarding the relationship of sustained timber yields and community stability as measured by employment in the timber industry.

There are a variety of social and economic changes over which local communities and the forestry profession have extremely limited influence. These changes include business cycles characteristic of timber and other extraction industries that create instability through changing demand (Berck and others 1992). Interest rates, labor productivity, changing consumer preferences, and international demand are larger economic forces that influence the stability of timber-dependent communities (Force and others 1993, Rasker 1994). For communities, the problem is cumulative. The community has little influence on the business decisions made by the firms operating in their area and the firms have little influence on macroeconomic forces that influence their operations.

Berck and others (1992) sought to examine the influence of timber industry characteristics against that of larger business cycles by separating the effects of being a small, isolated county with an open economy from those of being a county that is dependent on timber. They found that forestry has surprisingly low variation in employment, not significantly greater than that of manufacturing as a whole and much lower than agriculture or fisheries. What is different about forestry is the historic lack of diversity in community economies and their isolation (Berck and others 1992).

Federal regulations [36 CFR 219.12(g)(3)(iii)] pursuant to the NFMA require planning efforts to estimate the effects of alternatives on jobs and income (Schallau and Alston 1987). A growing body of literature argues that regional economic growth can be supported both by traditional extractive industries and by more indirect factors such as amenity values or quality of life (Power 1996). A complete view of economic impacts would examine both direct effects on extractive industries and indirect effects on attracting new business and capital with high quality of life.

Economic impact analyses (which estimate effects of alternatives on jobs and income) indicate how much the economic activity in a region might change as a result of management decisions. They do not indicate whether that change is desireable from society's standpoint. From a broad perspective, any income or employment lost in one region is likely to be gained elsewhere. For example, economic losses in a town affected by reduced FS timber sales may be offset by expansion in other logging communities or in communities producing substitute building materials. While possible economic losses are of great concern to the communities most affected by a policy change, offsetting gains in other communities means that economic impacts to a given community are not equivalent to the total economic costs or benefits. Considering only the jobs or income lost in one region and overlooking offsetting gains elsewhere overstates the net cost of a management action.

Timber Dependency

In response to the NFMA regulations, the FS developed a list of timber dependent communities in 1976 to assist national forests in choosing whether to permit exceptions to sealed bidding when they may endanger the stability of the communities. Timber-dependent communities were defined as those in which primary forest-products manufacturing facilities provided 10 percent or more of the total employment in the community. In 1987, this list was updated using the same definition of timber-dependency. First, the new list assigned communities to national forests and specified mill-dependent volume. Second, it noted that no widely accepted definition of dependency existed. Third, it acknowledged that communities depend on other forest resources in addition to timber.

The number of communities identified in each list as dependent is shown below:

Basin component, each state	1976 list	1987 list
Idaho	26	17
Montana	8	13
Washington	7	13
Oregon	16	23
Basin Total	57	66

Even though the FS articulated shortcomings in the approach to naming timber-dependent communities, making such a list added apparent legitimacy to this notion. Beyond the lack of a widely accepted definition and the recognition that communities may be dependent on other resources besides timber, the 1987 list added further confusion by using the terms "community," "economy," and "industry" interchangeably as in "community-wide share," "community supply," and "community volume under contract." Forest-products firms, not communities, bid on (and directly depend on) Federal timber sales. This

usage means that the distinction between industrial stability and community stability is often overlooked. Industry interests differ somewhat from the communities in which they are located. The dependency between a mill and national-forest-timber supply does not automatically translate to an economic dependency of the local community's economy on those national forest timber supplies (DeVilbiss 1986). The combination of the proportion of the work force and dependency on Federal timber might result in only a small part (as low as 3%) of the total workforce being dependent on national forest timber (Boyd and Hyde 1989).

The criteria used to create the FS lists do not account for important economic factors that affect the relationship between a community and local wood-products firms. Important economic factors include alternative sources of supply, proximity to larger labor markets, inter-mill competition for timber supply, inter-community competition for jobs, and changing technology and mill obsolescence. In today's market, the destination of Federal logs is unpredictable as processors reach far to supply their mills. Local mills will not necessarily be the successful bidder on Federal timber sales nor are local communities guaranteed to receive logging and processing jobs as a result of those sales.

We assessed the 66 communities on the 1987 list to see which ones could still be considered timber-dependent. We added two criteria to eliminate those that are well-connected to larger, diverse economies or are located in counties experiencing robust growth. In the first step, we eliminated those communities that were within 50 miles of other communities whose population was at least 10,000. We then eliminated communities in the 15 recreation counties (Johnson and Beale 1995). The remaining 29 communities represent those which are both isolated and in the slower growing parts of the Basin (see map 6.3). The list can be found in appendix 6-C. These communities are not necessarily less resilient than others (see the Social Assessment chapter). However, Federal land managers may want to focus on them when considering impacts of land management actions.

Change brought the forest industry to rural communities and, in fact, created many rural communities. It is change that is now bringing new industries into the Basin. Rapid social and economic change over the past two decades has complicated the nature of community dependence on Federal land (Society of American Foresters 1989). For example, in 1987, Orofino, Idaho was defined as a timber-dependent community. Its economy changed in the early 1970s when the Federal Government built the Dworshak Dam and a large fish hatchery. Today, Orofino is a destination for recreation tourism and its economy has become dependent on recreation (Force and others 1993). Opponents to the reservoir drawdowns claim that for each foot the reservoir surface is lowered, the community loses one million dollars in tourism revenue.

Economic Well-being

In much of the discussion in this and Social Assessment chapter, we have talked around the relationship between forest dependence and community well-being. The traditional bias among foresters that links sustained yield forestry with community stability has colored this issue. But the broader issue is whether the presence of forestland and the forest products industry are effective at promoting economic growth and development. This issue has been widely studied in forestry. Overdevest and Green (1995) provide a recent overview of the various studies and suggest a hypothesis that can be tested. Using data from rural counties in Georgia, they found that the well-capitalized pulp and paper industry is positively related to county per capita income. They also found that the solid wood products industry has no significant effect and that timberland concentration is negatively related to per capita income and positively related to the poverty rate. This latter finding supports Kromm's (1972) rejection of the axiom that "properly managed and utilized forest resource(s) insures economic well-being in forest regions."

Map 6.3— Timber-dependent communities, as defined in this chapter. These are communities both located more than 50 miles from another incorporated area larger than 10,000 people, and not located in a recreation county, 1995.

We tested the Overdevest and Green hypothesis[42] using county-level data from the Basin and found that neither the presence of forest-products processing facilities nor the acres of timberland (whether Federal, FS only, or private) can explain the variation in per capita income. The implication is that we have to reject the hypothesis that, in the Basin, timberlands or forest industries have a measurable affect on personal income. In the south, where this hypothesis has been accepted, forests are no longer viewed as positive drivers of economic growth. This finding is consistent with similar experience in international forestry situations (Winterbottom 1990).

Rejecting this hypothesis in the Basin suggests that the forest products industry has had a neutral impact on recent economic growth (the data set used was for 1993). Others (Rudzitis 1995, Power 1996) have pointed out the positive role that the scenic quality of forested landscapes have played in the recent economic growth.

Economic Growth[43]

In this section we deal with the development of regional economies in the Basin and the relationship between them and management of BLM and FS lands. It begins with a discussion of the resiliency of regional economies in the Basin, and then presents competing views among economists about the causes of economic growth. We then propose a new approach for viewing economic growth and the role played by BLM and FS management actions. This method looks at the total economy and examines expected trends. The importance of range and timber jobs can then be assessed against the backdrop of the overall economy and its trends. Finally, the type of analysis that would result from this approach is presented using the Tri-Cities BEA region as an example.

Economic Resiliency

In *A Framework for Ecosystem Management* (Haynes and others 1996), one of the assumed goals of ecosystem management was described as attempting to maintain ecological integrity and the resiliency of social and economic systems. Resiliency in this sense was defined as adaptability to change. Social or economic systems with high resiliency would be those capable of absorbing external shocks such as a recession and rebounding in terms of system indicators such as total employment and per capita income.

The adoption of this goal raises the challenge of how to measure economic resiliency. Preliminary research has found a high correlation between diverse economies and economic resiliency.[44] Diversity ratings for the BEA regions and counties in the Basin were calculated using the Shannon-Weaver index,[45] a statistic familiar to ecologists concerned with measuring plant and animal diversities. The employment diversity ratings for 1991 by BEA region are:

[42] We used county data to test whether per capita income was a function of timberland (federal, private) ownership; employment in wood products (SIC 24, 26); percent of the workforce in manufacturing (in one variant of the model we used this as an proxy for employment in wood products); and dummies for metro county status and whether the forest products industry had mills in the county. In the Overdevest and Green (1995) hypothesis, poverty rate was an important variable. Since there is only one federally designated poverty county in the Basin, we dropped this variable.

[43] This section was written by Amy L. Horne and Richard W. Haynes.

[44] Personal cmmunication. 1995. Ervin G. Schuster, U.S. Forest Service Intermountain Research Station, Missoula, MT.

[45] Personal communication. 1995. Greg Alward, U.S. Forest Service Land Management Planning Staff, Fort Collins, CO.

BEA region	Diversity Index
Boise	.81
Butte	.78
Idaho Falls	.81
Missoula	.81
Pendleton	.79
Redmond-Bend	.80
Spokane	.81
Tri-Cities	.79
Twin Falls	.78

These results are largely consistent with both our results and those in the Social Assessment chapter. The diversity indices indicate that the economies within the Basin are diverse (the highest possible score is 1.0) and, by correlation, have high economic resiliency. Little variation in economic diversity is found across the Basin. These findings make sense given our earlier discussion that per capita income is rising rapidly and few pockets of poverty exist (see "Overview" section of this chapter). Furthermore, the economy of the Basin has shown resistance to national recessions except when they greatly affect the agricultural sector.

The highest diversity ratings are for the Boise, Idaho Falls, Missoula and Spokane BEA regions. The BEA regions in which employment associated with recreation is substantial have high diversity ratings, suggesting that they have high resilience to fluctuations in recreation activity (Idaho Falls, Missoula, and Redmond-Bend). The two BEA regions in which timber plays a major role (Redmond-Bend and Pendleton) also have fairly diverse economies suggesting that they are resistant to fluctuations in that industry. The low diversity number for the Butte BEA region may be misleading because diversity was calculated for only that portion of the BEA region lying in the Basin.

Applying the diversity index at the county level provides a different picture requiring some care to interpret. The average diversity index for the 100 counties in the Basin is 0.70, much lower than the statistics calculated for each of the Basin BEA regions. We divided the set of diversity indices that were calculated for every county in the United States into thirds and defined the range displayed by the top third as "high" diversity, the middle third as "medium", and the bottom third as "low". Using these definitions, we found that 17 counties in the Basin have high diversity, 30 have medium diversity, and 53 have low diversity. A policy implication is that, if government wants to make a positive economic impact in counties with low diversity, an effective strategy in the long run would be to avoid distorting evolutions in economic structure, encourage diversification, and possibly mitigate transition costs.

This exercise also points out the hazards of analyzing economic activity at inappropriately fine scales. The BEA regions represent economically linked counties in which people commute between home and work. Thus, they are a reasonable scale at which to evaluate the ability of an economy to absorb external shocks.

Growth

Economists have argued about the causes of economic growth since the beginning of modern economics (Kindleberger 1965). From a theoretical standpoint, economic growth is the expansion path between sets of production functions that are explicit in time. The various theories of growth focus on traditional factors of production (labor and capital) and the role of technology in changing their productivities. Traditional regional economics views growth as a function of expansion in basic manufacturing industries. Contemporary challengers argue that other industries should be considered as part of the economic base (Power 1996, Rasker 1994, and Whitelaw and Niemi 1994). Both approaches recognize that some

locations have unique advantages or endowments that will attract certain types of economic activity. In the traditional view, these are resource endowments for extractive industries. In the contemporary view, these may include amenity or quality of life considerations.

The economic-base concept involves identifying the economic activities which form the foundation of a region's economy with the implication that anything that harms or lessens these activities threatens a region's economy. Careful practitioners divide every industry into the proportion that is exported (basic) versus that which serves local markets (non-basic). Proponents argue that basic activities help support non-basic activities by increasing the flow of money into and within an economic area. The subset of practitioners concerned with forest economics assert that jobs in the manufacturing sector are better than other jobs (Beuter 1995). No evidence exists to support the view that a dollar earned from exporting manufacturing goods is better than a dollar earned from exporting anything else. The economic-base approach is useful as a first approximation for characterizing the current conditions of a region's economy.[46] Where the economic-base approach gets into trouble is when it is used inappropriately as a tool for planning or predicting impacts of greater than one year in duration; a snapshot of current conditions tells little about the form a region's future economy may take.

We adopt the approach that economic growth of the Basin is dependent on those economic activities having excess employment. This is broader than the traditional approach used by the BLM and the FS when placing value on just the jobs in the ranching or manufacturing sectors. It assumes that the various comparative advantages, as expressed by various export sectors of the Basin, will continue to attract capital and labor to support long-term development. This follows the traditional neoclassical approach and takes for granted that factor supply (capital and labor) determines regional output and income while regional demand for goods and services is assumed to respond automatically to growth in production factors (Nijkamp and others 1986).

In the following discussion, we describe a process for discussing regional economic growth. We identify the key factors of regional economies and their relationship to public land management as population; the economy; jobs associated with range, recreation, and timber; and quality of life[47] (fig. 6.19). Trends that will change these key factors, regardless of BLM and FS policy, are population growth and structural changes in the economy.

Projections of structural changes in the economy can be obtained from the U.S. Bureau of Economic Analysis (BEA). The BEA projects structural shifts using the standard "shift-share" approach. They first develop national projections in gross national product (GNP) from projections of population, labor force, employment, and GNP per employee (U.S. Department of Commerce 1990). Employment within each industry is then projected as a damped extension of the industry's historical trend. Damped extensions mean that growth rates in one period are slightly less than in the previous one. The number of jobs in the United States in each sector are then distributed to states, substate areas, and counties according to the share of employment in that sector in the smaller area. Damped projections are used because of the assumption that self-limiting forces preclude the region from declining or growing at high rates for long periods (U.S. Department of Commerce 1992). These projections do not simulate fluctuations caused by business cycles, changes in societal preferences, or changes in technology.

[46] Krikelas (1992) provides a critical review. Nijkamp and others (1986) provide a comprehensive survey of various regional and multi-regional models.

[47] Quality of life can be defined as having three components: social amenities, scenic amenities, and recreation amenities. Social amenities include cultural opportunities and quality of public services and are related to population density. Some argue that quality of life is important to regional economic development because it attracts new business and capital (Power 1996).

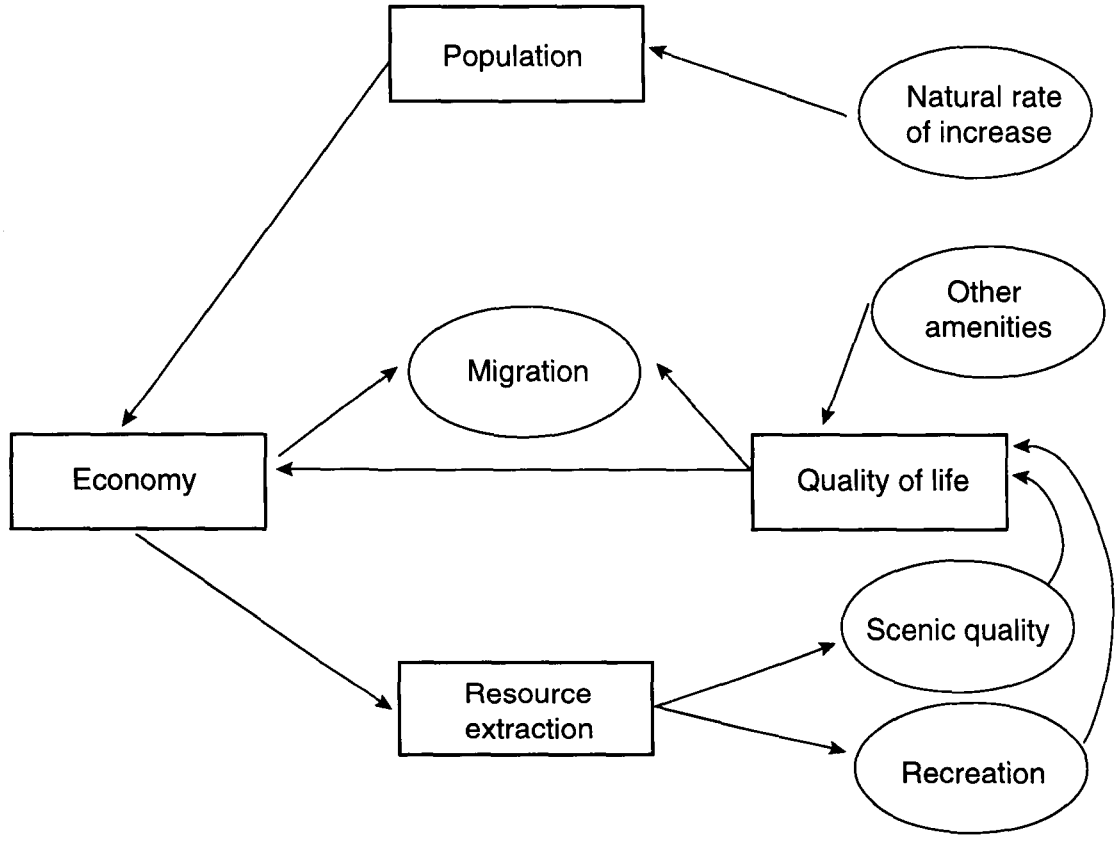

Figure 6.19— Model of regional economic growth.

Population can increase either through natural increase of a region's residents (births minus deaths) or migration. People already living in the Basin are responsible for most of the population growth that will occur in the next half-century because natural increase exceeds in-migration even if highest migration rates are assumed (McCool and Haynes 1996).

Migration can be viewed as responding to employment opportunities and the quality of life. When unemployment is low, in-migration occurs; when high, out-migration occurs. Quality of life attracts people when high and encourages people to move away when low. Capital and labor move when people migrate in or out of the Basin. Data on population growth can be obtained from the U.S. Bureau of the Census (1995) and Day (1993).

The FS and BLM can affect economic activity by the influence their management has on range, recreation, timber, and quality of life. For range and timber, the agencies can directly influence the number of jobs by setting levels of timber harvest and animal unit months. In both cases, jobs in the region can be associated with production from either public or private lands.

The agencies affect the supply of recreation opportunities primarily through their management of the road network: road building, road closures, and road maintenance standards. Building roads to harvest timber in previously unroaded areas presents a clear tradeoff between provision of primitive and roaded natural settings. The agencies also affect recreation by providing access to riparian areas and dispersed recreation sites. The quality of

the recreation experience is affected by the cumulative effects of management actions on scenic integrity. Provision of recreation-specific infrastructure, such as trails, ski-lifts, and campgrounds, is also important.

Currently, there is a great deal of recreation activity in the Basin. Recreation visitor days (RVDs) per resident average 31.5 compared to a national average of 22.3 RVDs per person (Cordell and others 1990). Demand for recreation is a function of population (see "Recreation" section above). At some point, the capacity of the land to support recreation activities becomes constrained due to congestion. At that point, recreation opportunities per person begin to decline.

Scenic integrity of a region results from the cumulative scenic quality of lands in all ownerships in the subregion: FS- and BLM-administered lands, other public lands, private industrial timberland, and other private land. The FS and BLM account for only a portion of the land base in any region. Changes in scenic quality resulting from increased residential and commercial use of private land as the population in the Basin grows may be a more significant factor in some places.

The Tri-Cities BEA Region Example

We explored the potential effect of FS and BLM policy on a regional economy using a model based on the discussion above and on figure 6.19. We ran the model five times, each time with a different set of assumptions about levels of AUMs and timber harvest set by the FS and BLM. The assumptions associated with each run are as follows:

Run	FS and BLM AUM	FS and BLM Timber Harvest
1	CCM	CCM
2	None	CCM
3	Double CCM	CCM
4	CCM	None
5	CCM	Double CCM

Where CCM refers to the quantities expected under continuation of current management. The results show that, given the assumptions described above, jobs in the Tri-Cities region associated with range are not affected by the levels of AUMs set on lands administered by the FS and BLM (fig. 6.20); only a small portion of that industry is dependent on public AUMs in this region. Similarly, jobs associated with recreation are little affected by FS and BLM management (fig. 6.21); decreases after the year 2030 are the result of the population's recreation demand not being met by the supply rather than FS and BLM levels of AUMs and timber harvest. Jobs in the timber industry are changed slightly when public harvest is either doubled or eliminated (fig. 6.22); most of the timber jobs in this region are supported by harvest from private timber land. The effects of FS and BLM levels of AUMs and timber harvest have very little effect on either population growth (fig. 6.23) or total personal income (fig. 6.24). The mode runs show that the economy of the Tri-Cities region is large and diverse. Rapid growth in other economic sectors overwhelms any impact caused by changes in FS and BLM policies either through their impact on range, recreation, and timber jobs or through their impact on recreation supply or scenic integrity.

Economics of Ecosystem Management

This section discusses a number of economic issues related to ecosystem management. Our primary emphasis is to provide an understanding of the market basket of ecosystem goods, functions, and conditions that society will want from the FS- and BLM-administered lands in the Basin over the next 50 years. This discussion may help shape the development of management directions that are economically efficient. We also discuss issues related to financing ecosystem management such as expenditures and revenue sources.

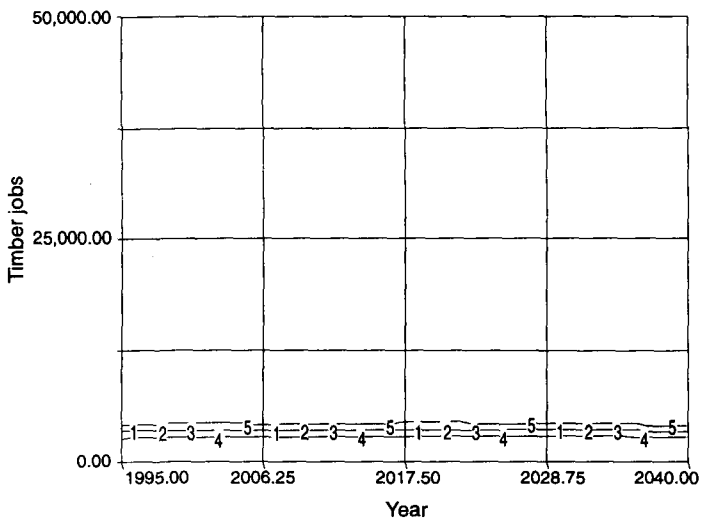

Figure 6.22— Effect of FS and BLM policies on timber jobs in the Tri-Cities BEA region.

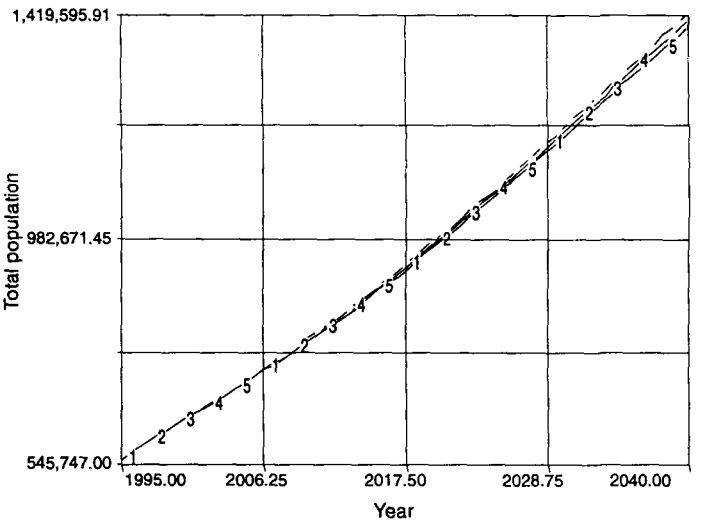

Figure 6.23— Effect of FS and BLM policies on population growth in the Tri-Cities BEA region.

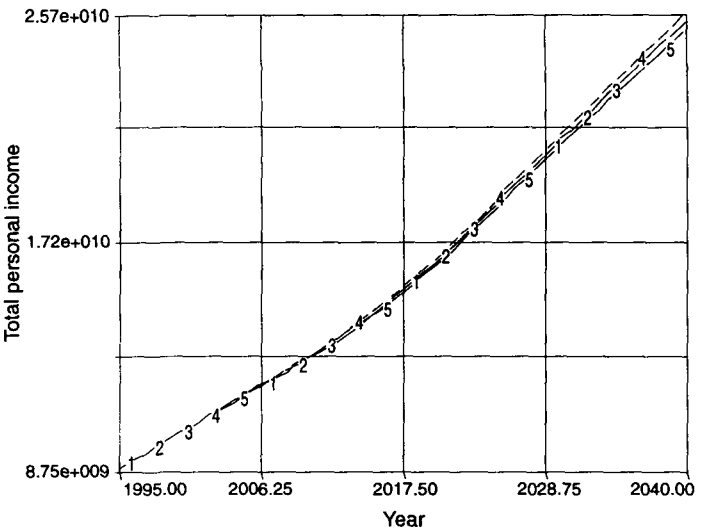

Figure 6.24— Effect of FS and BLM policies on total personal income in the Tri-Cities BEA region.

Key to figures 6.20 to 6.24

1 = AUMs and timber harvest at RPA levels

2 = Public AUMs = 0; timber harvest at RPA levels

3 = Public AUMs double RPA values, timber harvest at RPA levels

4 = AUMs at RPA levels, Public timber harvest = 0

5 = AUMs at RPA levels, Public timber harvest double RPA levels

Resource Valuation

A fundamental notion of stewardship is that land managers work to direct and maintain ecosystems to best fulfill objectives of owners (Smith 1986). The broadest view of societal interests is appropriate for public lands because their constituencies are extensive and diverse. Further, some types of outputs will only be available from public lands (Hyman 1973). An examination of the full array of the costs and benefits of ecosystem management requires a conscious attempt to value intangible benefits, posing problems for the social scientists who need to develop values and for biophysical scientists who need to develop explicit ecosystem output measures.

The FS- and BLM-administered lands in the Basin yield an array of conditions and outputs for the American people. Management directions chosen by FS and BLM managers can lead to changes in these conditions and outputs, thereby creating benefits and imposing costs (Freeman 1993). Resource valuation techniques (benefit-cost analysis) enable policy makers to explore the potential for substantial gains in economic welfare through better resource management (Freeman 1993). Resource valuation provides a framework and a set of procedures to help organize available information (Freeman 1993, Arrow and others 1996). It can help answer questions about what tradeoffs are involved in a given course of action (Freeman 1993). In this way, resource valuation can greatly improve the outcome of policy analysis by revealing preferences and opening up the decision making process for scrutiny.

Given that economics is the study of choices about the allocation of scarce resources between competing demands, providing decision makers with information about the nature of the tradeoffs involved in their decisions is appropriate. The development of sound forest and range management policies requires that consideration be given to the economic benefits associated with competing uses of forest and rangeland resources. The benefits that may be provided under different management regimes include both use values (such as those provided by timber harvesting and recreation) and non-use values, including existence value, option value, and quasi-option value. Many of these benefits are not revealed in market transactions, and thus cannot be inferred from conventional data on prices and costs. Recent developments in measurement techniques, however, have led to the estimation of these benefits for some forest lands (Vincent and others 1995).

Non-economists often express distrust of the values for nonmarket goods and dislike the expression of the preservation of endangered species in dollar terms. Such criticism misses the point that what lies at the heart of resource valuation is an approach to making choices among tradeoffs. These choices are made every day, both by government officials and private individuals, and the choices they make reveal implicit value (Freeman 1993).

Resource valuation is a criterion that can be used in different ways depending the question being asked. In one use it can be used to answer the question "what ought the FS- and BLM-administered lands in the Basin produce?" In another use, once goals and objectives are determined, it can also be used during implementation to identify the most cost-effective way to achieve those goals. Most people are familiar with this latter meaning. Here we use it in the former sense and define economic efficiency within the context of ecosystem management as producing the greatest market basket value of ecosystem goods, functions, and conditions possible from FS- and BLM-administered lands in the Basin.

Information from an efficiency analysis is not a sole criterion for decision making. Decision makers may have other objectives besides economic efficiency. They may be concerned with equity considerations, intergenerational effects, or the sustainability of resource systems or social risk aversion (Freeman 1993).

Outputs and Conditions to Consider

Ecological systems can be viewed as providing society with multiple outputs and conditions, and joint products (Freeman 1993). The basis for deriving measures of the economic value of changes in natural resource outputs is their effects on human welfare. Each individual's welfare depends not only on his or her consumption of private goods and government services but also on the quantities and qualities of nonmarket goods and services he or she receives from an ecosystem. Changes in outputs and conditions have their counterparts in changes in the asset value of the ecological system. The anthropocentric focus on economic valuation does not preclude a concern for the survival and well-being of other species. People can value other species for their uses but also as a source of existence or non-use value. Consequences that were once thought to lie outside the realm of economic analysis (such as the preservation of endangered species and unique ecological systems) are often central issues in the analysis of policy choices today (Freeman 1993). At the same time recent advances in the field of economic valuation make it possible to include in a resource valuation many outputs and conditions that were once considered unquantifiable.

Benefits to society from ecological systems include (1) inputs to the economy (wood and minerals); (2) amenities [opportunities for recreation, viewing wildlife, enjoying scenery, and services that are not related to any direct use of the environment (nonuse or existence values)]; (3) life-support services (clean air and water); and (4) dispersing, transforming, or storing residuals that are by-products of human and economic activity (Freeman 1993). For ecosystem management, we define ecosystem outputs as the ecosystem goods, functions, and conditions society wants the FS- and BLM-administered lands in the Basin to produce. "Ecosystem goods" are specific components of ecosystems such as minerals, timber, forage, mushrooms, huckleberries, salmon, grizzly bears, and grey wolves. "Ecosystem functions" are beneficial processes such as carbon storage and groundwater recharge. "Ecosystem conditions" refer to systemic, or integrated, states that people want to find on the land such as "old-growth" forests, roadless areas, beautiful scenery, and healthy ecosystems.

A "use" typology developed by economists helps to identify which ecosystem outputs to include in a resource valuation. These are outputs that have either consumptive uses, non-consumptive uses, or passive uses. An ecosystem good with consumptive use value is something which is removed from the ecosystem when used and does not remain for others to enjoy, such as timber. Consumptive use values can exist for goods traded in markets and goods for which no market exists. Other ecosystem outputs with consumptive uses include minerals, mushrooms, berries, floral greens, wildlife (to hunt), and fish (to catch).

People are also interested in non-consumptive uses which do not reduce what remains for others to enjoy, such as hiking on trails, viewing scenery, and birdwatching. Still others benefit from non-uses that do not involve direct use. Examples of non-uses are option (knowing a natural resource will be available for personal future use), existence (knowing a natural resource exists even when the likelihood of using it is small), bequest (knowing one's grandchildren will be able to enjoy a natural resource), and stewardship (knowing ecosystems are maintained in a healthy state) (Field 1994). Desires to maintain habitats and protect soils stem from complex motives including ensuring consumptive uses (game to hunt), non-consumptive uses values (birds to watch), and non-uses (maintaining soil productivity seems like good stewardship, and leaves productive ecosystems for future generations).

A list of the ecosystem goods, functions, and conditions that could be included in an ecosystem market basket is shown in table 6.36. Some of these outputs have already been discussed in the resource characterizations; other outputs have been mentioned in the discussions surrounding the ICBEMP: carbon storage, ecosystem health, fire risk, habitats, non-uses, scenic integrity, soil productivity, and water quality.

Table 6.36—Indicator variables for outputs from FS- and BLM-administered lands suitable for an ecosystem market basket.

Indicator Variable
Carbon Storage
Ecosystem Health
Fire Risk to Life and Property
Fish
Game
Minerals
Passive-use Values
Existence of Salmon
Existence of Other Threatened and Endangered Species
Existence of Unroaded Areas
Range
Recreation
Access (Roads)
Access to Riparian Areas
Scenic Integrity
Soil Productivity
Special Forest and Range Products
Timber
Visibility
Water Quality

Economic Characteristics of Outputs

The outputs and conditions from the FS- and BLM-administered lands in the Basin of importance to the American people have a mixture of economic attributes. Some, like timber, are market goods; economists expect markets to allocate timber resources efficiently. Other outputs and conditions have traits of nonmarket goods known as public goods, externalities, or common property resources. For nonmarket goods, market forces cannot be relied on to either allocate these resources efficiency, or to reveal their true values (Freeman 1993). Non-use values are a specific case of a public good, a type of good routinely addressed by resource valuation analysis (Kopp 1993). The non-use value of unroaded areas, for example, is available to all without the possibility of exclusion; one person's enjoyment does not interfere with the enjoyment of others; and, one may enjoy them without any monetary expenditure.

Adding Up Values

The economic value of an ecological system is defined in the literature as the sum of the discounted flows of all the outputs and conditions (Freeman 1993). We differ in that we display flows of the values of outputs and conditions over time rather than the discounted flow. The reason for this is to avoid the controversy over which discount rate is appropriate to use and to let decision makers choose how to distribute benefits and costs between human generations.

There is a substantial and growing body of literature that suggests that healthy forest ecosystems provide substantial non-use value to the American public. If forest management decisions are to be based on sound economic principles, such values must be taken into account. Non-use values associated with forest preservation are potentially very large, and could by themselves dominate the values associated with extractive use (Loomis 1994). For example, estimates of willingness-to-pay for old growth forests west of the Cascades range from $48 to $144 per U.S. household per year (Hagen and others 1992). In another example, Olsen and others (1991) found that households in the Pacific Northwest were willing to pay between $26 and $74 per year to double the size of the salmon and steelhead runs in the Columbia River.

Ignoring non-use values such as existence value and option value may seriously understate the benefits associated with the preservation of wilderness areas, wildlife, old forests, and other goods associated with preservation (Kopp 1992, Vincent and others 1995). In natural resource damage assessments, practitioners recognize that excluding

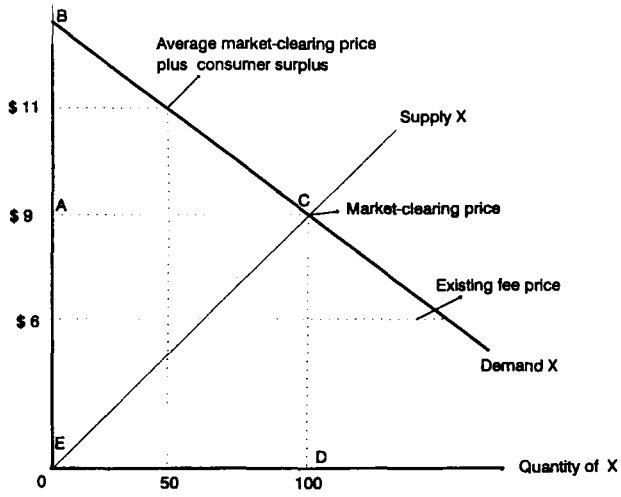

Figure 6.25— Net economic value is the area under the demand curve less the cost of production, here represented by the triangle ABC.

non-use values results in an inefficiently low price signal to those undertaking risky activities, which can lead to more than the optimal number of accidents. The courts have ruled that damages should be set so as to compensate for the full loss in economic value of the resource, where full value explicitly includes non-use value *(Ohio v. United States Department of Interior,* 880 F 2nd 432, D.C. Cir. 1989). A recent study of chinook salmon in the Yakima River calculates their total value as the sum of existence, commercial, recreational, capital, and other values (Anderson and others 1993).

Determination of Values

The question of the values of natural resources in a resource valuation context is often misunderstood and a source of controversy. Some people are distrustful of economists' penchant to extend economic measurements to non-market outputs and to reduce as many variables as possible to monetary measures (Freeman 1993). Dollar values have the advantage of translating the importance of outputs into a common metric by which their relative importance can be assessed. "Willingness-to-pay," the economic value beyond cash flow to producers, is the appropriate measure. Net economic values are the appropriate measure for such an analysis. They are measured as the amount consumers are willing to pay less the cash flow to producers. Since many of these outputs are not bought or sold in markets and do not have market prices, the economic value of them may be quite different from their market value (Freeman 1993). For market goods, net willingness-to-pay equals total willingness-to-pay minus actual payments. In figure 6.25 it is equal to the triangle ABC. For outputs and conditions for which no market data exist, economists have determined that techniques such as travel cost and contingent valuation are appropriate for determining natural resource value (Arrow and others 1996). It is important for the value of all outputs and conditions to be measured using the same accounting stance (U.S. Department of Agriculture, Forest Service 1990). Once this is done it is possible to add the values of market and non-market outputs, and compare the sum of values from different market baskets.

Weighting these outputs by the value society holds for them is an essential part of the process. Knowing how much of each output or condition an ecoregion can produce is the first step but the relative importance of these outputs is not known until all the outputs have been weighted by their values. It is incorrect to define an ecoregion as being efficient for timber production solely because it has higher timber growth than other ecoregions. First, the timber values may be low if the ecoregion is far from timber markets or processing facilities. Second, timber values must be compared with societal values of other outputs from that same ecoregion. An ecoregion with high timber values relative to other ecoregions may also have recreation values that exceed its timber values. Thus, the appropriate course for managers is to plan actions with the total market basket of values for a given ecoregion in mind.

Unroaded areas—A central principle of ecosystem management is to maintain options for future generations. One option to maintain is "unroaded areas," defined as undeveloped public land and water that does not have roads, buildings, mines, clearcuts, or other related development. This definition includes areas having these attributes whether or not they have special status (such as a designation as Wilderness or as a Wild and Scenic River). Unroaded areas have been a central component underlying the debate over management of Federal lands for the past 40 years. The values of unroaded areas have been documented in numerous studies (Barrick and Beazley 1990, McFadden 1994, Pope and Jones 1990, Walsh and others 1984a). Including the value of unroaded areas in a resource valuation for ecosystem management introduces a measure of ecosystem condition.

Unroaded areas are viewed as national assets wherever they remain throughout the United States (Walsh and others 1996), hence the appropriate scale of demand to consider is national. Seventy percent of the unroaded areas greater than 200,000 acres remaining in the lower 48 states lie within the study area ("Recreation" section of this chapter, above). Walsh and others (1996) found that U.S. citizens have an average willingness-to-pay for unroaded areas in the Rocky Mountains of $49 and in the Pacific Coast of $47, with regional differences shown in the tabulation below:

	Region of unroaded area	
Region of resident	Rocky Mountains	Pacific Coast
North	$43	$37
South	$56	$49
West	$55	$65

Pope and Jones (1990) found that residents of Utah were willing to pay $53 per household per year for 2.7 million additional wilderness acres, and $92 per household per year for 16.2 million acres.

The study by Walsh and others (1996) found that people believe that Alaska has the highest quality of unroaded areas by far. The next highest quality unroaded areas are located in the Rocky Mountains, with those in the Pacific Coast ranked a close third. Respondents ranked the unroaded areas in both the Rocky Mountains and Pacific Coast as high for both use and existence values. Both areas received high ratings for a number of existence values including: protecting rare and endangered species, protecting air and water quality, preserving unique plants and animal ecosystems and genetic diversity, knowing that natural areas exist for their own sake, and knowing that future generations will have natural areas.

Walsh and others (1996) also found that use-values of the unroaded areas in the Rocky Mountains and Pacific Coast regions received high ratings for conserving natural areas for educational and scientific study, and for the option of visiting them in the future. About one-half of the respondent households said they had seen natural areas in the Rocky Mountains (53%) and Pacific Coast (46%). Between eight and nine households in ten expressed an interest to see natural areas in both regions in the future. About 93 percent of the households in the west were interested in seeing unroaded areas in the Rocky Mountains and the Pacific Coast. Residents in the east and south had nearly as high an interest in visiting unroaded areas in the Rocky Mountains (84 and 89% respectively) and Pacific Coast (81 and 83% respectively).

Methods

The resource valuation approach involves: (1) defining the spatial areas and time periods to be analyzed, (2) determining how much of each output will be available from each geographic area over the time period, (3) determining the value of each output from each geographic area over the time period, (4) multiplying the amount of each output over the time period by its value, and (5) summing the total values of the outputs for each geographic area in the time period. We call this sum the "market basket." It provides an integrated picture of the benefits possible from FS- and BLM-administered lands in the Basin within the constraints of ecosystem processes and time.

The spatial areas we used for analysis were the Basin and its component ERUs (see map 6.2). These can be thought of as areas having particular abilities to supply outputs desired by society. We made projections for a period of 50 years.

The outputs for which we had quantified projections, and thus could include in this analysis, were range, recreation, timber, and the unroaded areas (including designated wilderness). The projected quantities of AUMs and timber were from other staffs and are uncertain.

The assumptions we had to make to project recreation activity are described in the "Recreation" section of this chapter. In brief, we obtained the current number of acres in each of the three Recreational Opportunity Spectrum (ROS) classes in each ERU from the spatial data collected for the project. We assumed no change in these numbers over the 50-year projection. We assumed that participants in recreation activity on the FS- and BLM-administered lands in the Basin live in the seven states which contain part of the Basin (Idaho, Montana, Nevada, Oregon, Utah, Washington, and Wyoming). We obtained projections of the population in this area and its characteristics from the U.S. Census Bureau (Campbell 1994, Day 1993).

To project the existence value of unroaded areas in the Basin, we assumed they would not change over the next 50 years. We obtained the current number of unroaded areas in the Basin from the project's Spatial Analysis Team. We assumed that the number of households benefiting from the existence of unroaded areas in the Basin was the number of households in the United States. Projections of the number of households in the United States were taken from the U.S. Census Bureau (Campbell 1994, Day 1993).

We used the RPA values (U.S. Department of Agriculture, Forest Service 1990) for range, recreation, and timber because the values of all resource outputs were developed in a consistent manner and are commensurate with one another (tables 6.37 and 6.38). We have used different values for the ERUs whenever available. All RPA values were determined "on forest" or "on range." This means that none of them include the value added with final processing. Thus the benefit for range is related to forage, not beef sold to consumers. Likewise, the costs of components that are associated with an activity but that are not an output from Federal lands are not included. The recreation values do not include the costs of camping equipment or fishing gear; the timber values are stumpage prices plus consumer surplus.

There are no estimates of the willingness-to-pay for the existence value of unroaded areas in the FS- and BLM-administered lands in the Basin, so we inferred a value from Walsh and others (1984a) and Pope and Jones (1990). We first developed an equation for the total value (recreation plus existence value) of unroaded areas from Pope and Jones (1990). We used Pope and Jones (1990) to derive the total demand curve because their study is more recent and their estimates of willingness-to-pay are the lower of the two. We then used Walsh and others (1984a) to calculate the percent of value attributable to existence value for a given amount of unroaded land, and applied this percentage to the total demand curve. The resulting equation for the household willingness-to-pay for the existence of unroaded areas is (fig. 6.26):

cents/year = 4.05E-5 + 3.4718 * (1/1,000 unroaded acres)

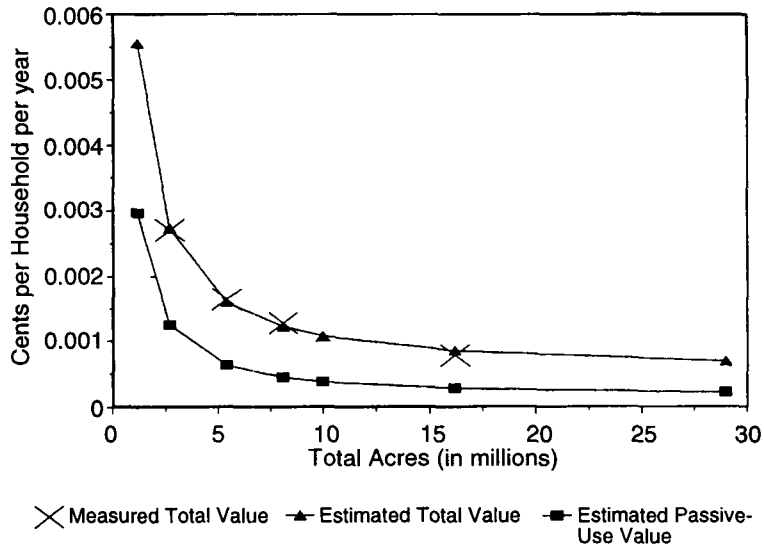

Figure 6.26— Passive-use value per acre of unroaded land.

Table 6.37—Willingness-to-pay values[1] for carbon storage, range, and recreation outputs by Ecological Reporting Unit (ERU) in the Basin, 1994 dollars.

Output	ERU 1-6	ERU 7-9	ERU 10-13
	..... 1994 Dollars		
Carbon Storage (per ton)[2]	65.00	65.00	65.00
Range (per AUM)[3]	8.66	8.66	8.66
Recreation (per person activity day)[4]			
Camping	9.27	6.44	7.25
Day Use	9.27	6.44	7.25
Fishing	54.66	41.40	41.40
Hunting	46.71	48.73	47.72
Motor Boating	2.39	2.39	5.98
Motor Viewing	4.78	4.04	3.33
Non-motor Boating	3.59	9.56	8.37
Off-road Vehicles	4.78	4.04	3.33
Snowmobiling	4.78	4.04	3.33
Trail Use	7.21	6.84	6.74
Viewing Wildlife	31.15	29.80	28.35
Winter Sports	40.26	40.26	40.26
Wilderness[5]	35.65	23.78	23.88

Source: U.S. Department of Agriculture Forest Service (1990). Unless otherwise noted, inflated to 1994 dollars using consumer price index (Council of Economic Advisors 1995).

[1] All willingness-to-pay values are determined "on-forest" and do not include other production costs associated with an activity.

[2] Personal communication. 1995. Steven Winnett, Environmental Protection Agency, Washington, DC.

[3] Personal communication. 1995. Linda Langner, U.S. Department of Agriculture, Forest Service, Economist, Washington, DC. Inflated from 1993 dollars using producer price index.

[4] From U.S. Department of Agriculture Forest Service (1990), inflated from 1989 to 1994 dollars using consumer price index. An "activity day" is the average amount of time spent during 24 hours pursuing that activity. These values include fees but exclude expenditures that represent a cost of production such as travel costs.

[5] Additional value when activity takes place in wilderness area.

The number of unroaded acres in the Basin is within the range of the data collected by Pope and Jones (1990). There are two uncertainties associated with this equation. First, we do not know if the willingness-to-pay for unroaded lands in the Basin is different from the value for lands in Colorado (Walsh and others 1984a) or Utah (Pope and Jones 1990). Second, we do not know the effect of shifting the spatial scale of demand. Both Walsh and others (1984a) and Pope and Jones (1990) estimated demand of state residents for wilderness areas designated within their own state. We have applied this value to all U.S. households. We do not know that people in the east, for example, hold the same existence value for unroaded lands in the Basin as residents of the Northwest; their values could be more or they could be less.

Table 6.38—Willingness-to-pay values for timber and chip outputs by Ecological Reporting Unit (ERU) in the Basin, 1994 dollars.[1]

Ecological Reporting Unit	Timber[2]	Chips
	Dollars per thousand board feet	
Northern Cascades (1)	165.15	144.08
Southern Cascades (2)	124.72	124.72
Upper Klamath (3)	486.67	144.08
Northern Great Basin (4)	294.09	144.08
Columbia Plateau (5)	410.64	144.08
Blue Mountains (6)	255.30	144.08
Northern Glaciated Mountains (7)	222.93	144.08
Lower Clark Fork (8)	179.50	144.08
Upper Clark Fork (9)	136.94	136.94
Owyhee Uplands (10)	11.66	11.66
Upper Snake (11)	56.78	56.78
Snake Headwaters (12)	63.10	63.10
Central Idaho Mountains (13)	428.91	144.08

[2] Willingness-to-pay is calculated by adding stumpage price and consumer surplus estimated as 10 percent of stumpage price.

Results

The current market basket value per acre of FS- and BLM-administered lands (fig. 6.27) is highest in the Central Idaho Mountains (ERU 13), Southern Cascades (ERU 2), Northern Cascades (ERU 1), Snake Headwaters (ERU 12), and Lower Clark Fork (ERU 8). Recreation is the dominant value provided in most ERUs. The exceptions are that timber provides the greatest value in the Upper Klamath (ERU 3) and the existence value of unroaded areas provides the greatest value in the Northern Cascades (ERU 1), Northern Glaciated Mountains (ERU 7), Snake Headwaters (ERU 12), and Central Idaho Mountains (ERU 13). Recreation value per acre is highest in the Southern Cascades (ERU 2), Lower Clark Fork (ERU 8), and Central Idaho Mountains (ERU 13). The existence value per acre of unroaded areas is highest in the Central Idaho Mountains (ERU 13), Northern Cascades (ERU 1), and Snake Headwaters (ERU 12). The per acre value of timber is highest in the Southern Cascades (ERU 2), Upper Klamath (ERU 3), Central Idaho Mountains (ERU 13), and Upper Clark Fork (ERU 9). The per acre value of range is highest in the Upper Clark Fork (ERU 9), Lower Clark Fork (ERU 8), and Northern Glaciated Mountains (ERU 7); this value exceeds $1 per acre only in the Upper Clark Fork. The market basket used in this analysis is incomplete and contains only items for which we could develop values. A more complete analysis would include values for ecosystem health, fire risk, and carbon storage, among others.

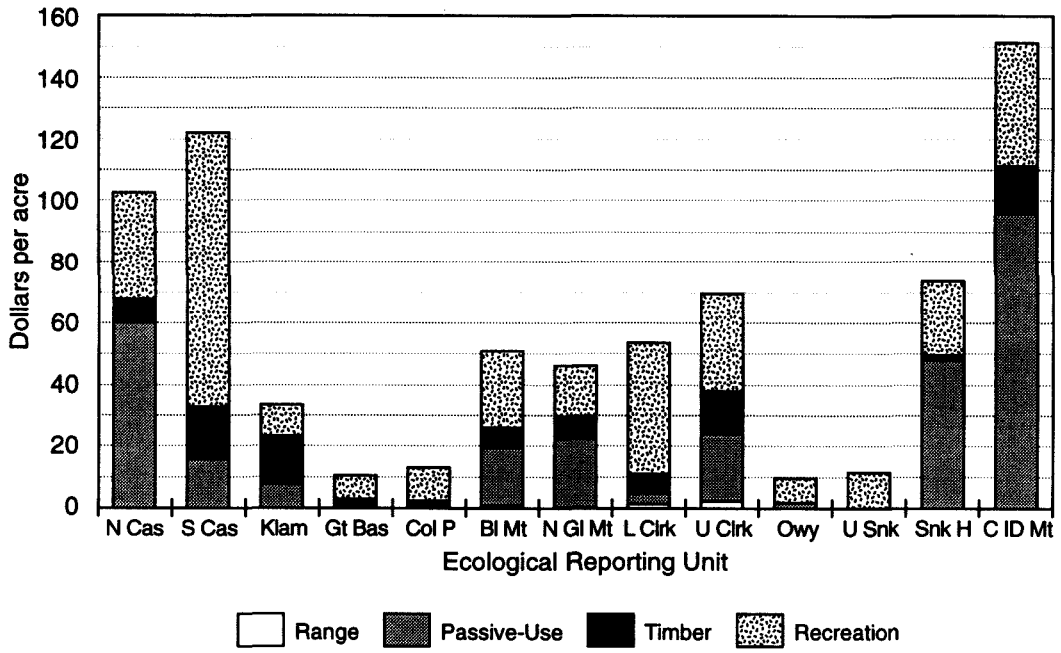

Figure 6.27— Current market basket value of FS- and BLM-administered lands, per acre, within each Ecological Reporting Unit.

Using projections of values and outputs, we can estimate how the relative importance of the various outputs will change over the next 50 years. The tabulation below shows the relative importance of those outputs providing 90 percent of the value provided by FS- and BLM-administered lands in the Basin for the years 1995 and 2045:

Activity	1995 Value	2045 Value
	..... Percent	
Camping	3.45	4.40
Day Use	5.28	8.11
Fishing	9.88	6.64
Hunting	9.48	6.31
Motor Viewing	1.88	9.46
Timber	11.49	5.38
Trail Use	3.28	6.85
Unroad Existence	46.86	41.43
Winter sports	5.05	5.70

As this tabulation shows, the existence of unroaded areas is by far the most valuable output from FS- and BLM-administered lands in the Basin today, and will continue to be so in the year 2045 (fig. 6.28). The relative importance of other outputs will probably shift over time. Today, the three most highly ranked uses from FS- and BLM-administered lands in the Basin are the traditional ones of timber, fishing, and hunting. Our projections indicate that by the year 2045 the three most highly valued uses will be motor viewing, day use, and trail use. This suggests that the FS and BLM will face a fundamental shift in their constituencies. It also suggests that the objectives of land management activities might be different in the year 2045 than they are today. For the Basin as a whole, the relative importance of wildlife viewing, motor and nonmotor boating, range, off-road vehicle (ORV) use, and snowmobiling provided by FS- and BLM-administered lands are less than those activities in the above tabulation.

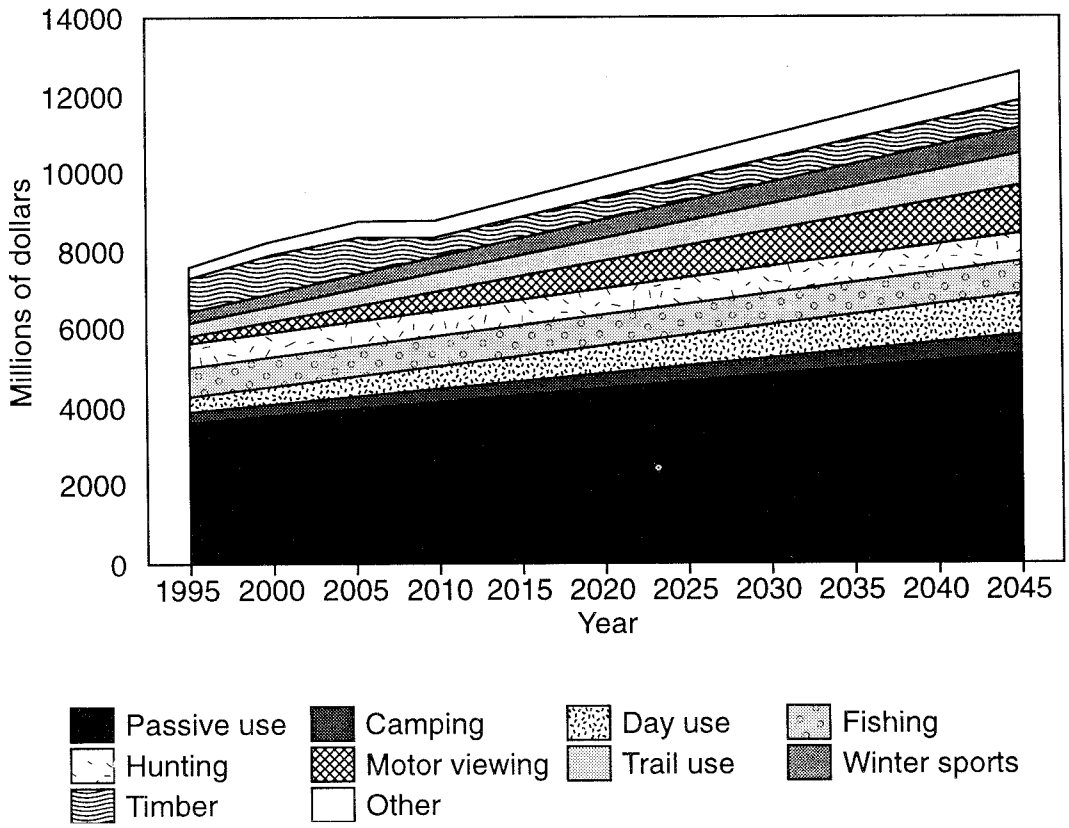

Figure 6.28— Projected increase in value of benefits from FS- and BLM-administered land, by activity, 1995-2045.

Given their differences in natural resource endowments, road infrastructure, unroaded areas, proximity to population centers, and age and income characteristics of residents, each ERU is predicted to provide society with a different bundle of benefits. In most ERUs in the coming decades there will be a re-ordering of priorities, generally toward recreation. Detailed information is shown in table 6.39. Table 6.40 shows the three outputs having the highest relative importance for each ERU in the year 2045. Outputs marked with an asterisk (*) are predicted to increase in relative importance by 10 percent or more over the 50-year period.

In the Southern Cascades ERU and Central Idaho Mountains ERU, the outputs having the highest relative importance in the year 2045 are similar to those for the Basin as a whole: existence of unroaded areas, motor viewing, day use, and trail use. Other outputs are predicted to have high relative importance in other ERUs. Camping will assume a high relative importance in the Upper Klamath ERU and Owyhee Basin ERU. Fishing is predicted to have a high relative importance in the Upper Great Basin ERU, Columbia Plateau ERU, and Upper Snake ERU. Hunting will probably have high relative importance in the Columbia Plateau ERU, Upper Clark Fork ERU, and Upper Snake ERU. Timber will probably be highly important in the Upper Klamath ERU, Upper Great Basin ERU, Columbia Plateau ERU, Northern Glaciated Mountains ERU, and Lower Clark Fork ERU. Viewing wildlife will become highly important in the Northern Cascades ERU. And finally, winter sports will probably be highly important in the Upper Snake ERU and the Snake Headwaters ERU.

Table 6.39—Percent of total value provided by individual activities for each Ecological Reporting Unit (ERU), 1995 and 2045.

Table 6.40—Ecosystem outputs currently having greatest relative value from each Ecological Reporting Unit (ERU).

ERU	Outputs with greatest relative value
Northern Cascades	Unroaded existence, motor viewing*, viewing wildlife*
Southern Cascades	Motor viewing*, Unroaded existence, day use
Upper Klamath	Unroaded existence*, timber, camping
Upper Great Basin	Motor viewing*, fishing, timber
Columbia Plateau	Fishing, timber, hunting
Blue Mountains	Unroaded existence, day use, fishing
Northern Glaciated Mtns	Unroaded existence, timber, motor viewing
Lower Clark Fork	Unroaded existence*, timber, day use
Upper Clark Fork	Unroaded existence, hunting, trail use
Owyhee Basin	Motor viewing, trail use, camping
Upper Snake	Winter sports, fishing, hunting
Snake Headwaters	Unroaded existence, trail use, winter sports
Central Idaho Mtns	Unroaded existence, day use, motor viewing

* Increases in relative importance by 10 percent or more by the year 2045.

Scenarios

We used scenarios to address the uncertainty inherent in the projections of timber harvest, grazing levels, recreation activity, and unroaded areas. Scenarios are simplifications that provide a tool for gaining an integrated understanding of biophysical and social systems, and how and to what extent management actions affect them. They are not EIS alternatives; they do not necessarily comply with existing laws and regulations. The uncertainty in the projections results from risks and imperfect knowledge. By varying the assumptions made to address these uncertainties, we can identify those assumptions that make significant differences in the outputs of different management regimes. The procedure starts with development of a series of themes to explore; we chose, as described below, "continuation of current management," "passive management," and "active management."[48]

These scenarios were used in early SIT integration efforts and were developed around five themes: timber harvest, roads, riparian areas, human communities, and biophysical and social processes. Each of the scenarios reflected a different management approach as suggested by its name.

The continuation-of-current-management scenario explores the consequences of maintaining the types and levels of management activity and outputs from Federal lands characteristic of the late 1980s. The road network is assumed to be unchanged and maintained. Timber harvest and silvicultural treatments, including salvage harvesting, are assumed to follow the recent trend. Livestock grazing is assumed to trend slightly downward as Allotment Management Plans are completed.

The passive-management scenario assumes no commodity production from public land. This scenario assumes that no new roads are built and that no road maintenance occurs. Recreation is

[48] There was a fourth, consumptive demand, for which we were unable to project recreation outputs.

affected because roads become impassible over time, particularly in highly erodible areas. It assumes no timber harvesting, no silviculture treatments, and no livestock grazing.

The active management scenario assumes management of natural resources on public lands is aimed toward having healthy, functioning ecosystems. This scenario assumes a small reduction in the road network overall. Some construction of new roads occurs in a manner that reduces adverse effects on watershed and terrestrial systems; this is offset by closing some existing roads to restore or maintain watershed processes. Timber harvesting, salvage, and silvicultural treatments are assumed to focus on achieving forest structures and compositions that reduce risks of fire, insects, and pathogens. Livestock grazing on FS- and BLM-administered lands is assumed to initially decrease by 20 percent while restoration takes place and then gradually return toward current levels.

The specific projections of road density, provided by the Landscape Ecology staff, assumed the following increases in primitive/semi-primitive acres (and decreases in roaded natural acres) under the scenarios as:

Scenario	Increase in Primitive /Semi-Primitive	ERUs
	Percent	
Continuation of Current	0	All
Active Management	5	1,2,3,6,7,8,9,12,13
	0	4,5,10,11
Passive Management	10	1,7,8
	6	2,6,9,12,13
	0	3,4,5,10,11

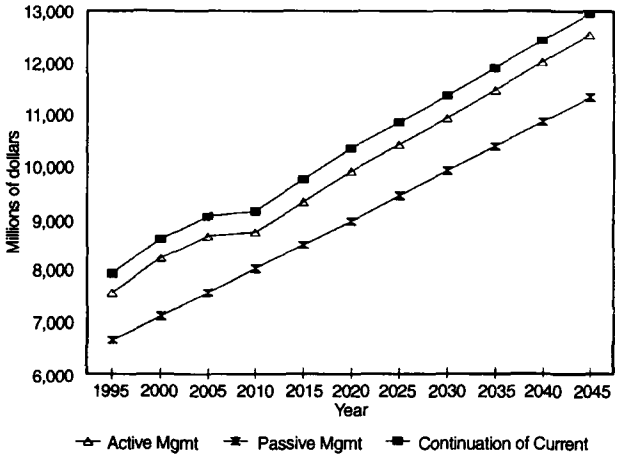

Figure 6.29—Projected annual value of scenario outputs, including range, recreation, timber, and existence of unroaded areas. Scenarios include active-management, passive-management, and continuation-of-current-management, 1995-2045.

Caution should be used in interpreting these results because the market basket used in this analysis is incomplete. It is presented to demonstrate a comparative analysis of use to decision makers. A more complete analysis would include differences between scenarios in ecosystem health, fire risk, carbon storage, among others.

This incomplete market basket analysis indicates that the continuation-of-current-management scenario provides the highest values overall, followed by active management and passive management (fig. 6.29). People who benefit from range and recreation would prefer continuation of current management. It is the least desirable scenario from the perspective of providing existence-of-unroaded-area values which currently comprise 47 percent of the ecosystem market basket. The active management scenario would be first choice for people benefiting from timber harvest, and second choice for all other outputs. In 2045, compared to the continuation-of-current-scenario, active management represents an annual loss of 12.3 million dollars in range, 12.4 million dollars in recreation benefits, an annual gain in benefits of

61.6 million dollars for existence of unroaded areas, and 8.3 million dollars in timber benefits. The passive-management scenario produces the lowest benefits in all categories except the existence of unroaded areas, for which benefits are 86.8 million dollars per year greater in 2045 than under the continuation-of-current scenario. Losses of 49.4 million dollars per year in range, 665.9 million dollars per year in timber, and 527.9 million dollars per year in recreation would result under the passive management scenario.

In all these scenarios the relationship between roads and recreation value changes over time. In the first decade, reductions in road densities increase recreation benefits. In subsequent decades, this relationship shifts until, by the year 2045, reductions in road densities decrease recreation benefits. This flip-flop occurs because of the projections of population growth and age structure in the seven northwest states.

In the year 2045, the value of the current road network for recreation is considerable because it provides access for motorized recreation. By this time, even small reductions in road densities decrease recreation benefits significantly. The recreation activities with highest total value have a common need for roads. Roads are important as resources themselves for activities such as motor viewing and cross-country skiing. They also provide access to trailheads and recreation sites such as campgrounds and day use areas. Closely linked to roads is the issue of access to riparian areas which are important for high value activities such as fishing and viewing wildlife. An economic study of the PACFISH[49] strategy found the greatest losses in benefits resulted not from reduced timber or range values, but from the effects of prohibiting recreation activities in the riparian zone (Bolon and others 1995).

[49] PACFISH is a comprehensive strategy for improved management of habitat for Pacific salmon and steelhead on FS- and BLM-administered lands. The two agencies developed the strategy in 1992 and 1993 (PACFISH 1994, 1995).

Our findings suggest that road closure policies should be examined in light of their simultaneous impacts on multiple factors: fish, wildlife, and recreation. The agencies might be able to identify other methods of achieving the same ecosystem management goals without compromising their ability to meet future recreation demand. For example, rather than closing roads that cause ecosystem damage, agencies could focus on maintaining or redesigning roads to reduce the harm. Although the public may want to protect salmon stocks and prevent the spread of exotic plants, it may feel that being denied access to public lands is too high a price to pay for these benefits.

A clear tradeoff exists between providing road access for some types of recreation and providing primitive and semi-primitive recreation settings for others. Primitive or semi-primitive areas by definition have few or no roads. Fifty-six percent of trail use in the Basin takes place in these low road density settings. Trail use is highly valued in both the Northern Cascades and Central Idaho Mountains ERUs, yet so are activities dependent on roads. Defining the appropriate balance between the amount of roaded natural and primitive/semi-primitive settings is a question that needs further study.

Scenic integrity is another important element of high value recreation activities such as motor viewing and day use. This suggests that placing emphasis on landscape appearance when developing plans or activities could be beneficial, particularly in areas where these activities are a significant percentage of total recreation value. For example, silvicultural prescriptions could be aimed toward assuring a natural appearance and avoiding sharp edges or contrasts.

Complementarity

The efficiency challenge to the land management agencies is shown in figure 6.30 for two outputs: timber harvest and scenic integrity. The curve represents a "production possibility frontier"—the set of all combinations of timber harvest and

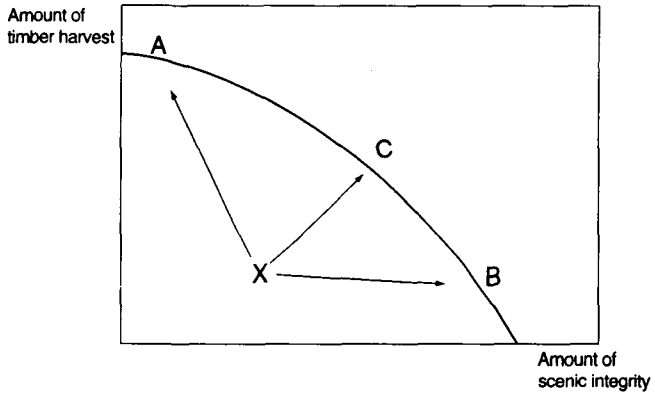

Figure 6.30— Hypothetical joint production function between timber harvests and scenic integrity showing opportunities to increase output of both.

scenic integrity with no waste and no inputs left over from which more of one output could be achieved without giving up some of the other. If our current position is at point X, society could be better off if we moved closer to the production possibility frontier. The problem is that people wanting scenic integrity are afraid that a change will mean a move toward point A at which less scenic integrity will be provided. Similarly, people wanting timber harvest are afraid that change will mean a move toward B at which less timber harvest will occur. Resistance to change means we forego opportunities to move toward C at which more of both scenic integrity and timber harvest are provided and everybody is better off. The challenge is to identify points like C, and the path to reach them, when there are multiple desired outputs. Figure 6.30 presents a challenge to find opportunities for complementary ecosystem management such as point C that allow us to provide greater social benefits with the resources of FS- and BLM-administered lands.

Expenses of Ecosystem Management

The agency costs of ecosystem management are a matter of budget and cost-accounting. Lacking a specific definition of ecosystem management (the activities, area, and time period it involves), it is impossible to estimate its budgetary costs. Some expenditures associated with future risks (such as fire fighting or controlling exotic species) are notoriously unpredictable.

If ecosystem management means increased complexity in agency activities and accounting, it will probably increase disputes over accounting practices. Allocation of direct and indirect costs from relatively straightforward activities such as timber harvest and trail construction is already a matter of dispute among accountants, policy-makers, and stakeholders. For example, witness the two-decades-long debate over below-cost timber sales and range improvements. Already thorny issues are road costs, administrative overhead, pooling of expenses, dedicated funds such as Knutson-Vandenburg (KV), and fire losses.

Another problem is that incentives exist to maximize budgets rather than efficiency (Sumner 1994). Therefore, cost savings from one decision are reallocated elsewhere. In theory, savings could occur. For example, reducing the timber sale program in anadromous drainages as part of a conservation plan for salmon could save 147 dollars in expenditures for every thousand board feet (MBF) of timber not put up for sale (Haynes and others 1992). In some accounting approaches this means that savings would be available for other programs or locations.

One aspect of ecosystem management is ecosystem restoration. Restoration includes three broad categories of activity: returning disturbed or damaged ecosystems to a previous condition, altering the trajectory of existing ecosystems to achieve more desirable future ecosystems (for example, a different stand composition), and restoring missing parts of the landscape (late-seral stages, for example).

The explicit consideration of ecosystem restoration is a significant change in land management. American society traditionally has under-valued sustaining the productivity of land, assuming that enough extra land was available as a low-cost substitute for lost productivity of degraded land.

As a new management practice, ecosystem management focuses attention on analytical processes to determine the appropriate level of restoration. This decision framework requires an integrated understanding of the biological, physical, social, and economic consequences of alternative decisions. Scientific and technical information alone is not sufficient to determine whether a given restoration project should be undertaken. To be efficient, the net benefits of restoration must be found to be greater than the net benefits of mitigation or inaction. In some cases, society's interests may be served best by natural processes with no inputs of human labor and capital.

Revenues for Ecosystem Management

Ecosystem management with its all-inclusive focus on a wide range of goods, functions, and conditions includes many resources that are not formally owned or that are held in common trust. Hardin (1968) described this phenomenon and the associated human behavior as the "tragedy of the commons." In essence, when a resource is publicly available for use, there is an incentive for overuse since there are no incentives to save resources for the future: anything left by one person can be used now by another. As use increases without regulation, depletion of the resource stocks quickly follows as individuals attempt to maintain income or benefits. The collapse of various ocean fisheries is a classic example of this behavior.

Prices are extremely strong signals of human preferences and modifiers of human behavior. Periods of rising prices, for example, point to resource scarcity. Consumers respond by using less, producers respond by making more. Much of current land management's dilemma stems from attempting to discern society's wishes in the absence of price signals. For example, providing free recreational opportunities means that the FS and BLM cannot impartially gauge how people respond to various alternatives other than through planning processes that are vulnerable to influence by special interests.

The ICBEMP is charged with identifying what is required to maintain sustainable or harvestable levels of plant and animal species. Broad indicators suggest that Basin-wide we are already sustaining timber inventory. Other outputs, particularly recreational settings and special products, lack price signals that could moderate use. Given current levels of recreation and harvesting of firewood, publically grown Christmas trees, mushrooms, and berries, these resources may face the "tragedy of the commons." Because these valuable resources are available to the public at little or no cost, there is little incentive for harvesters to conserve these resources. The increases in population predicted for the Northwest suggest that demands on ecosystems and public resources will continue to increase. Charging fees for recreation and special products could protect ecosystem conditions in recreational settings, maintain sustainable or harvestable levels of species, and provide the FS and BLM with sources of revenue more in keeping with the outputs society wants.

Related to the issue of user fees are Federal distributions to county governments [the FS's 25-Percent-Fund and "payments in lieu of taxes" (PILT) used by both the FS and BLM].[50] In the case of the FS's 25-Percent-Fund, these distributions are currently determined from timber sales and grazing permits. Our present focus on ecosystem management demonstrates that the economic value and societal importance of Federal lands has evolved as use increases and unique natural attributes become more scarce. However, this increased value does not now translate into more funds for local governments. Projected recreation value is far in excess of projected timber supply values in the Basin, but recreation contributes little value to local governments to support schools, infrastructure, and public services. This evolution implies that changing the formula for calculating Federal compensation to local governments could better pass along to counties the full

[50] Schuster, E.G. June 26, 1994. Report on 25-Percent-Fund and PILT payments to Montana counties: FY94-FY95. 31 p. Unpublished report. On file with: U.S. Department of Agriculture, Forest Service, Intermountain Research Station, Missoula, MT.

spectrum of values held for FS- and BLM-administered lands in the Basin.

The difference can be illustrated by comparing payments based on timber and range with non-commodity uses such as recreation value. Using data from CRBSUM (the spatially-explicit model developed by the SIT Landscape Ecology Staff) and from the market basket approach described earlier, we can estimate current and potential payments from the 25-Percent-Fund made by the Federal agencies to the 100 counties in the Basin.

	Total Value	Current Payments	Potential Payments
	..... Millions of dollars		
Range	33.0	8.2	8.2
Recreation	3,326.0	0.0	415.7 - 831.5
Timber	1,379.0	344.8	344.8
Total	4,737.0	353.0	768.7 - 1,184.5

The lower number given for recreation assumes recreational activity is reduced by half by charging fees; the higher number assumes fees have no impact on recreation activity. This emphasizes a policy topic that is of potential importance to local communities, that is, the Federal Government's collection of the true value of Federal-land-produced goods and services and the sharing of this value with local governments. Existing mechanisms that compensate local governments for the non-taxable status of Federal lands apply only to revenue actually generated from Federal lands. Recreation is a high value that increases use of Federal lands. However, it generates little revenue and can impose substantial costs on local governments for roads and emergency services.

It has been suggested that the environmental amenities available on Federal lands adjacent to some communities provide a quality of life that generates economic growth; this in turn contributes to communities through a larger tax base and greater economic activity.[51] Our example suggests that another approach to supporting counties is through modifying the formula that determines Federal payments to counties to reflect the change in uses of Federal lands.

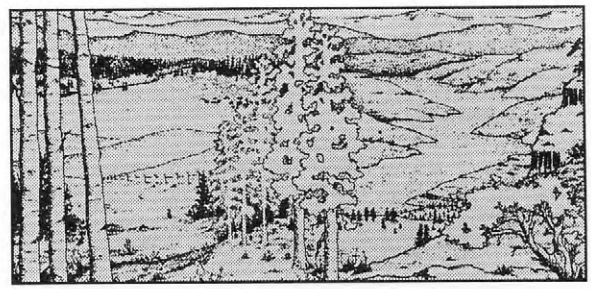
Sustainability

The term "sustainability" has intuitive appeal but is difficult to define. Sustainable forest management has been defined as that which "meets the needs of the present without compromising the ability of the future to meet their own needs" (World Commission on Environment and Development 1987). In the aftermath of the United Nations Conference on Environment and Development held in Rio de Janeiro in June 1992, the participating governments have been developing criteria and indicators for the conservation and sustainable management of temperate and boreal forests. In February 1995, the group working on this task produced the Santiago Declaration, which has been signed by the United States. This declaration identifies seven broad criteria to be used for describing, assessing, and evaluating a country's progress toward forest sustainability. Criterion 6 is the maintenance and enhancement of long-term multiple socioeconomic benefits to meet the needs of societies. The 19 indicator variables address five socioeconomic themes, including

- production, consumption, and recycling of wood and non-wood products,
- recreation and tourism (area, visitor days, facilities),
- investment in the forest sector (research and development, education, technology for forest growth, health, and management, processing, recreation and tourism),
- cultural, social, and spiritual needs and values (including non-consumptive values), and
- employment and community needs (jobs, wage and injury rates, viability and adaptability to changing economic conditions, and amount of forest used for subsistence).

[51]Rudzitis, G.; Watrous, C.; and Johansen, H. 1995. [Manuscript]. Attitudinal survey of Upper Columbia River Basin Residents. Moscow, ID: University of Idaho Department of Geography. [not paged].

Two things should be noted about this list. First, the list of indicators to be tracked is long, reflecting the extreme complexity of sustainability. Second, the diversity of what is to be sustained means that tradeoffs and complementarities are involved. It is unlikely that all indicators can be sustained at current levels. Innovative perspectives are needed if management directions that meet multiple objectives are to be revealed.



For the Basin as a whole, broad criteria of sustainability indicate that we can and are sustaining forest acreage and inventory volumes. But this comes with the cost of shifting timber harvest from the Basin to other regions in the southern United States and in Canada. For the United States, these changes do not alter the indicators of sustainability; rather, they shift changes from one region of the United States to another. For other criteria indicators, comparisons are more difficult given the problems of measuring any but the simplest indicators of sustainability consistently across regions and nations. This does not address a number of indicator variables, but many of them reflect value judgments and are not measurable with today's science.

For the Basin as a whole and for broad regions within it, the notion of sustainable human communities is difficult to define. With populations expected to double in the Basin, the more pertinent question is how resilient are the communities and their associated economies? Change in the Basin is being driven by population growth, both in the form of in-migration and rates of natural increase that are higher than the U.S. average. Sustainability has the connotation of status quo when associated with the word "communities." A more useful focus would be on the attributes of communities and economies that can accommodate change. Underlying these comments are expectations about economic growth both in total and in the mix of activities. In another sense, much of the thought underlying notions of sustainable communities is the notion that their economic base lies in the nearby resource endowments. In an almost Jeffersonian fashion, proponents speak of sustaining communities and their associated economies on timber, minerals, fish, ranching, and farming activities. The reality in the Basin is quite different. It is true that agriculture plays a major role in the economies of the Basin, especially in the Twin Falls, Tri-Cities, and Pendleton BEA regions. But for the most part, more than half of the Basin's economy is in the financial, trade, and service sectors. The mining and manufacturing sectors account for less of the economy than the national average for those two sectors. Finally, rather than focusing on what seems to be an outdated concept, it may be more profitable to focus on how communities and economies are adapting to change.

CONCLUSIONS

A fundamental tenet of land stewardship is for managers to direct and maintain ecosystems to fulfill the objectives of the owners. For the FS and BLM, providing a broad array of ecosystem goods, functions, and conditions is appropriate because it is required by laws and regulations and their constituencies are extensive and diverse. The economic challenge of ecosystem management for these agencies is threefold: to produce the bundle of ecosystem goods, functions, and conditions that society wants (economic efficiency), whose distribution of benefits is according to societal wishes (equity), without adversely affecting economic activity. We address each of these issues in turn. At the end, we briefly characterize the economic issues related to fish, minerals, range, recreation, and timber.

Economic Efficiency

Under current management, FS- and BLM-administered lands in the Basin provide society with a wide array of benefits. The current and future importance of the benefits that we could measure and value is shown in table 6.41. This table shows that of the ouputs and conditions we were able to evaluate the existence of unroaded areas is a highly valued condition on FS- and BLM-administered lands in the Basin today. It will continue to be so in the year 2045 although to a lesser degree. The relative importance of other outputs will probably shift over time. Existence values aside, the three most highly ranked uses from FS- and BLM-administered lands in the Basin today are the traditional ones of timber, fishing, and hunting. Our projections indicate that by the year 2045 the three most highly valued uses will be motor viewing, day use, and trail use. This suggests that the FS and BLM will face a fundamental shift in their constituencies. It also suggests that the objectives of land management activities might be different in the year 2045 than they are today. For the Basin as a whole, the relative importance of wildlife viewing, motor and nonmotor boating, range, off-road vehicle (ORV) use, and snowmobiling provided by FS- and BLM-administered lands are less than activities just discussed and are included in the "other" category in table 6.41.

Given their differences in natural resource endowments, road infrastructure, unroaded areas, proximity to population centers, and age and income characteristics of residents, each ERU is predicted to provide society with a different bundle of benefits. In most ERUs in the coming decades there is predicted to be a re-ordering of priorities, generally toward recreation.

The institutional framework and societal desires from public land stewardship continuously evolve. In the course of U.S. history, major land management themes have changed from privatization (1800-1891), to conservation and scientific management (1891-1945), to commodity production (1945-1960), to increasingly complex and contentious demands (1960-present). Today, the agencies are faced with attempting to balance these

Table 6.41— The relative importance of some outputs from FS- and BLM-administered lands in the Basin, for the years 1995 and 2045.

Activity	1995 Value	2045 Value
	Percent	
Camping	3.45	4.40
Day Use	5.28	8.11
Fishing	9.88	6.64
Hunting	9.48	6.31
Motor viewing	1.88	9.46
Timber	11.49	5.38
Trail Use	3.28	6.85
Existence value of unroaded areas	46.86	41.43
Winter Sports	5.05	5.70
Other	3.35	5.72
Total	100.00	100.00

traditional issues with demands for ecosystem health and fire management. Society's objectives for public land stewardship will likely continue to change.

Broad indicators suggest we are sustaining forest acreage and inventory at the Basin-level. Given current levels of recreational activity and harvesting of firewood, publicly grown Christmas trees, mushrooms, and berries, along with some other Federal resources, potentially face the tragedy-of-the-commons. Because these valuable resources are available to the public at little or no cost, there is litte incentive for harvesters to conserve these resources. The increases in human population predicted for the Northwest suggest that demands on ecosystems and public resources will continue to increase. Establishing a fee system for recreation and special products could protect ecosystem conditions in recreational settings, maintain sustainable or harvestable levels of species, and provide new sources of revenue.

Equity

The benefits of the FS- and BLM-administered lands in the Basin are distributed widely. Consumers of beef or timber benefit because these goods are traded in national markets. People who enjoy knowing unroaded areas exist may never visit the Basin yet receive benefits. Millions of people, mostly residents of the Basin and the Northwest, recreate here; there is little difference in participation rates among people with different lifestyles.

About 220,000 jobs are associated with current levels of range, recreation, and timber harvest on FS- and BLM-administered lands. Range accounts for 1 percent of these jobs, recreation 87 percent, and timber 12 percent. In addition, jobs are associated with mining and with harvesting special forest and range products, but the number is unknown.

Federal distributions to county governments from revenue sharing are currently determined from timber sales and grazing permits. Yet some of these counties bear costs associated with recreation such as infrastructure, road maintenance, and emergency services. Including the value of recreation on Federal lands in payments to counties could double or triple their revenues.

Economic Activity

The Basin

Agriculture and agricultural services remain economic strengths of the Basin. The Basin has a large, diverse economy of 1.5 million jobs that is enjoying above average rates of growth. Per capita income is growing faster than the U.S. rate, and the poverty rate is generally lower than the U.S. average. The past two decades have seen rapid population growth, and the evolution of what was a mature, resource-based economy into a diverse economy oriented toward technology, transportation, and service sectors.

We expect the general economic growth in the Basin to continue sustained by in-migration in some areas. Growth is expected in services, finance, insurance, real estate, trade, and agricultural services. Fastest growth is expected in the service sector, which includes health, business, educational, and legal services. The manufacturing, farming, and government sectors are expected to decline as a percent of the economy over the next 50 years.

Traditional regional economics views growth as a function of expansion in basic manufacturing industries. Contemporary challengers argue that other industries should be considered part of the economic base. Both approaches recognize that some locations have unique advantages or endowments that will attract certain types of industries. Traditionalists view these as resource endowments for extractive industries. In the contemporary schema, these include amenity or quality of life considerations that attract business, capital, and skilled labor. Our findings indicate that changes in management strategies by the FS and BLM have little impact on the economy of the Basin or its subregions using either of these two approaches. The effects of the agencies may be more pronounced at specific local levels, however.

The nine regional economies in the Basin are diverse, and they are resilient to changes in FS and BLM commodity outputs. Overall, the forest-products industry has had a neutral impact on recent economic growth. We found no relationship between economic well-being at the county level (expressed as per capita income) and either the forest-products processing facilities or the presence of timberlands, whether Federal, FS only, or private. Basin-wide the cattle industry accounts for 29 percent of agricultural sales, but only 7 percent of it is dependent on BLM and FS forage. Recreation accounts for 14.6 percent of the jobs in the Basin. Mining accounts for 0.5 percent, but we were unable to acquire data to determine what percent of mining jobs is attributable to FS and BLM resources.

The Boise BEA region is strong in agriculture, agricultural services, transportation, finance, insurance, and real estate. The portion of cattle dependent on Federal forage is 12 percent, above the Basin average.

The Butte BEA region is the only regional economy in the Basin without a strong agricultural sector. Mining is very important there along with transportation and services.

The Idaho Falls BEA region is strong in agriculture, agricultural services, construction, and trade. Mining is important, though less so than in the Butte BEA region. Both employment attributable to recreation (30%), and the portion of cattle dependent on Federal forage (11%), are above the Basin average.

The Missoula BEA region is strong in agriculture, agricultural services, construction, and transportation. Employment attributable to recreation is 31 percent, considerably above the Basin average.

The Pendleton BEA region is strong in agriculture, agricultural services, and manufacturing. Both forest products and food processing are important components of its manufacturing sector. Economic diversity is fairly high, suggesting this economy is resilient to fluctuations in the forest-products industry.

The Redmond-Bend BEA region is strong in agriculture and agricultural services. Both employment attributable to recreation (25%), and the portion of cattle dependent on Federal forage (9%), are above Basin averages. Forest products and food processing are both important components of its manufacturing sector. Like the Pendleton BEA region, economic diversity is fairly high, suggesting this economy is resilient to fluctuations in the forest products industry.

The Spokane, Tri-Cities, and Twin Falls BEA regions all are strong in agriculture and agricultural services. In addition, the Spokane BEA region is strong in trade, and the Twin Falls BEA region is strong in construction. None of these regional economies is likely to be affected by changes in FS and BLM commodity outputs.

Counties

Counties grouped according to a typology of income specialization or other characteristics exhibit different patterns of economic behavior. Those dominated by the service sector have consistently shown the highest rates of economic and population growth since 1970; they have also exhibited high resiliency, rebounding faster than other counties after the early 1980s recession. These include counties with trade-center towns and growing recreation and tourism economies. Counties dominated by recreation or retirees have shown consistently high rates of growth in population, total employment, and total personal income over the last 20 years. Between 1979 and 1989, counties in which manufacturing income is dominant showed the highest tendency to evolve to a different kind of economy. Many of these did so because of losses in the wood products or mining sectors.

Community Economies

Maintenance of stability in timber-dependent communities is often thought to be the responsibility of the FS despite their having no specific legal mandate to do so. No facts document a link between sustained timber flow and community stability. What makes timber communities less resilient than others is their tendency to be isolated and lack economic diversity. These traits make their economies sensitive to changes in interest rates, labor productivity, consumer preferences, and national business cycles, all factors over which the FS and BLM have little influence.

In 1987, the FS identified 66 Basin communities as timber-dependent. Today, 29 exhibit characteristics indicating concern may be legitimate for their sensitivity to Federal timber sales. These are isolated communities separate from fast-growing populations and economies in the Basin. Federal policies toward such communities are more accurately viewed as political, not economic, and reflect political preferences about equity or distribution of wealth. Given that human populations in the Basin are expected to double over the next 50 years, the notion that any community may maintain stability is questionable. The more appropriate question is what attributes of communities and their economies best accommodate change.

Characterizations of Specific Resources

Fish

Through a multitude of actions of others such as ocean fishing, government hydropower projects, irrigated agriculture, forestry, and grazing, the FS and BLM are managing some of the last remnants of good quality habitat for declining fish stocks. The net result of these actions, plus habitat degradation, has been the virtual elimination of a valuable commercial fishery. It has also meant incalculable damages to the American Indians for

whom salmon was economically, culturally, and spiritually significant. Spiritual values aside, the greatest value of the much diminished Columbia Basin fishery currently is for recreation, much of which takes place on public lands. The burden on the FS and BLM to maintain habitats that support strong fish populations will probably increase as human population growth and associated land-use changes, commercial fishing pressures, climatic influences on ocean habitat, and fish passage through hydropower facilities continue.

Minerals

There is a smaller percent of mining employment in the Basin than in the Nation (0.45% vs 0.66%), but mining is very important in the six counties that account for 70 percent of the Basin's mineral production value. The Basin produces 30 percent of the Nation's silver, 12 percent of the Nation's phosphate, and 11 percent of the Nation's gold.

Future mineral production will occur in the Basin at rates that will depend on metal prices, laws, and regulations. The extent to which mining activity will affect public lands is difficult to know. The greatest probability for mineral development in the long-term is along three geologic trend-lines which run through six ERUs. One is a northeasterly trend from southeastern Oregon into central Montana (the Owyhee, Central Idaho Mountains, and Upper Clark Fork ERUs), in which the most economically attractive targets include copper, cobalt, and large, low-grade deposits of gold and silver. In the western Northern Glaciated Mountains and North Cascades ERUs, mining for gold and silver will likely continue. This mining will be underground in the short-term, but become open pit mining in the future. Considerable base metal resources lie in a northwesterly trend from southwestern Montana into northeastern Washington (Upper Clark Fork, Lower Clark Fork, and Northern Glaciated Mountains ERUs). Large-scale open-pit mining and processing of phosphate ore is likely to continue in the Snake Headwaters and Upper Snake ERUs over the long term.

Range

The dependency of the livestock industry on BLM and FS forage varies from 1 to 11 percent in the BEA regions, with a Basin-wide average of 7 percent. Sales of cattle dependent on BLM and FS AUMs average 2 percent of total agricultural sales across the Basin. Many of the counties that are most highly dependent on Federal forage have small sales of cattle and calves, suggesting that their rangelands are of low productivity. If current trends continue, forage use will decrease on BLM lands by 18 percent, and on FS lands by 19 percent, over the next two decades.

On average, holders of BLM or FS grazing permits run bigger operations that are more profitable than those of non-permittees. Permit acreage and AUMs are skewed toward the largest permit holders—a small number of individuals, corporations, and partnerships.

Recreation

FS- and BLM-administered lands in the Basin provide over 200 million recreation activity days per year, valued at $1.0 billion per year (in terms of willingness-to-pay). This is over 80 percent of the recreation value provided by all Federal lands in the Basin. At present, recreation on FS- and BLM-administered lands has a higher willingness-to-pay value than the market value of timber or range outputs in every ERU, except in the Klamath Basin in which timber values will be surpassed by recreation by the year 2005. Fishing provides the greatest benefits of all activities ($300 million), followed by day use ($250 million), downhill and cross-country skiing ($230 million), hunting ($146 million), and camping ($75 million). By the year 2045, the most value to the larger and older human population will be provided by (in decreasing order) motor viewing, day use, trail use, fishing, and hunting.

The FS and BLM manage over 90 percent of the federally owned recreation acres in almost every ERU and ROS class in the Basin. Seventy-five percent of all activity days take place in roaded

natural settings (road densities between 1.7 and 4.2 miles per square mile). Roads and access to riparian areas are an aspect of recreation supply common to what will be the most highly valued recreation activities for the next 50 years. If charged, recreation fees could be used to finance road maintenance, and to offset other potential decreases in road funds.

Purchases of food, equipment, lodging, transportation, licenses, and other items associated with recreation on public lands add up to significant expenditures and support some 220,000 jobs in the Basin. The percentage of the job force supported by recreation is above the Basin average in the Idaho Falls, Missoula, and Redmond-Bend BEA regions.

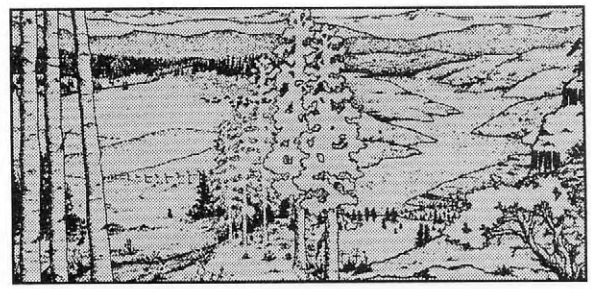
A tradeoff exists between access for some types of recreation and primitive/semi-primitive recreational settings for others. Seventy percent of the unroaded areas of 200,000 acres or greater in the lower 48 states lie in the Basin; 56 percent of trail use in the Basin takes place in the primitive/semi-primitive settings. Trail use is highly valued in both the Northern Cascades and Central Idaho Mountains ERUs, yet so are activities dependent on roads. Finding an appropriate balance between roaded natural and primitive/semi-primitive settings will need further study.

Scenic integrity is another important element of high-value recreation activities such as motor viewing and day use. Managers might consider using silvicultural prescriptions that improve scenic integrity by creating a more natural appearance, and avoiding sharp edges or contrasts, particularly in ERUs such as the Northern Cascades and Central Idaho Mountains that are expected to be highly valued for motor viewing and day use.

Special Forest and Range Products

Little is known about the special forest and range products industry in the Basin because data on jobs and harvest are not regularly gathered. Compared with the industry west of the Cascade Mountains, the industry in the Basin is small but growing and focused around wild edible mushrooms and huckleberries. Rapid expansion in the special forest and range products industry in the Basin is expected to continue. Under the present permitting system and without a fee system, some of these species may be over-harvested.

Timber

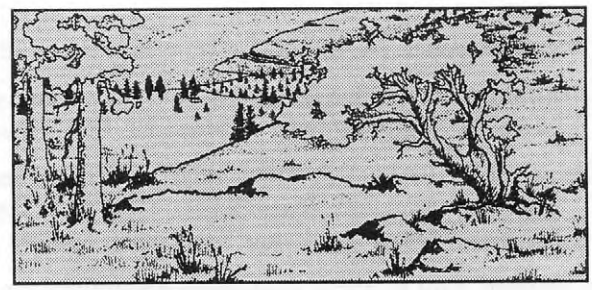


Softwood timber harvest in the United States is projected to increase by 35 percent (0.6% per year), to 14.6 billion cubic feet by the year 2040. In the past five years, Federal harvests have been shifting from western to southern states, such that western states now account for 45 percent of total timber harvest. Timber harvest in the Basin currently accounts for 10 percent of total U.S. harvest; it has declined by 7 percent since 1986 and is expected to decline another 5 percent by the end of the decade. FS and BLM harvest is currently 46 percent of total harvest in the Basin.

In recent years, the number of timber jobs in Idaho and Montana has declined due to technological improvements; no such trend exists for eastern Oregon and Washington. Based on current harvest projections, we expect modest employment declines to continue, related to declines in timber harvest. More than 80 percent of the timber harvest in the Basin occurs in the Spokane, Missoula, Redmond-Bend, and Pendleton economic areas; this includes both private and public timber.

Water

Current water use in the Basin (34.3 billion gallons per day) is almost entirely (93 percent) for irrigated agriculture with only minor amounts used for domestic, commercial, and industrial purposes (5 percent), and livestock (2 percent). Southern Idaho accounts for 62 percent of the water withdrawals. Projections based on per capita water use for commercial, domestic, and industrial water purposes suggests potential conflict over water use between municipalities and irrigators. Eight out of nine economic areas would have to reduce the amount of land in irrigated agriculture to meet municipal needs.



Water use and water policies, while not controlled by the FS and BLM, do affect land management in the Basin. For example, the listing of chinook and sockeye salmon in the Snake River has caused reconsideration of land management practices. In addition, changes in water allocation is one of the options available for ensuring the viability of fish populations. Complicating the water issue is the impact of increasing demands for water based recreational activities many of which take place on federal lands.

INTRODUCTION

Human use of natural resources in the Basin is a major determinant of ecosystem conditions. Over time, human uses have changed dramatically, resulting in equally dramatic effects on the land, water, air, and other species. Human values regarding ecosystems have changed as well, as have the economic needs of an increasingly complex society.

To understand how people relate to and interact with the environments in which they live or have an interest, it is essential to recognize that people are part of the ecosystem, both in the sense of being another species dependent on ecosystem components and because humans determine how ecosystems are socially defined, studied, and managed. The public and federal agencies agree that ecosystem management should consider this "human dimension" of ecosystems. Past management has not adequately accounted for the linkages between people and their environment, the ways people affect the environment, the cultural and spiritual values people place on environments, and the meanings that people attach to specific areas and localities.

The Human Dimensions Task Group (1993) describes six types of information important to understanding the human component of ecosystems: historical context, perceptions of resource character, existing social conditions, existing managerial situation, societal needs and demands, and the effects of humans on ecosystems. Corresponding regional efforts have also been developed that list principles and related strategies for incorporating the human dimension into ecosystem management (Human Dimension Study Group 1994). Our understanding of nature and human relationships with the environment are cultural expressions used to define who we were, who we are, and who we hope to be at this place and in this space (Greiger and Garkovich 1992).

Purpose and Objectives

This social assessment incorporates the human dimension into ecosystem management by characterizing the values, processes, and conditions that are the human components of ecosystems. This assessment also explains the tradeoffs among these components that may be acceptable to society. The overall goal of the social assessment is to inform decision-makers about the social, political, and cultural context of their decisions and to provide information helpful in defining and addressing important policy questions and public issues. Two specific objectives of the assessment are:

- To describe in a variety of ways the people who either live, or have an interest, in the Basin. Emphasis is given to the issues confronting people living in the Basin relative to past and proposed natural resource management.
- To discuss interactions between people and their environments, particularly the recreation, scenic quality, and cultural and emotional dimensions, as well as the influence and response of political and institutional structures to these interactions. This discussion includes some social implications of changing economic conditions in the Basin as described in chapter 6, the Economic Assessment.

The social assessment is integrated with other sciences. The Economic Assessment is a close companion to the Social Assessment; the two should be read in combination for a more complete understanding of socioeconomic issues. In some ways, the other assessments (chapter 3, Landscape Dynamics; chapter 4, Broad-scale Assessment of Aquatic Species and Habitats; and chapter 5, Terrestrial Ecology) are social assessments as well, by virtue of their focus on conditions produced in part by humans and because they reflect human values by the emphases assigned to various topics.

The social assessment may be helpful not only to decision-makers, but to people who live in the Basin and others who care about the physical, biological, social, and economic conditions of Basin ecosystems. Because this social assessment is the first attempt at describing the types of social values and forces that help shape ecosystems Basinwide, however, it should be viewed as a starting point for societal discussion, rather than an end point.

Rationale for the Social Assessment

General reasons for including people in ecosystem assessments are listed and discussed below:

- People are concerned about the environment.
- Human actions affect the environment.
- Agency management of public lands affects people.
- The Federal Government holds certain trust responsibilities with respect to American Indians.
- The natural environment holds significant symbolic values for people.

Environmental Concern

People are concerned about their futures, the influence of environmental quality on those futures, and the condition of the environment. Surveys and public opinion polls demonstrate that environmental concern has been strong since Earth Day in 1970. Jones and Dunlap (1992) show how support for the environment has been stable or increasing, with the vast majority of Americans favoring increased environmental protection. The same trends are present among Basin residents. However, these attitudes vary by topic and among different populations of respondents. Therefore, to develop appropriate policy there must be a better understanding of environmental concerns, the acceptability of various management practices, and people's preferences for implementing management.

Human Effects on the Environment

In a biological sense, humans are transfer agents of energy and matter. Studying the dimensions of these human transfers, just as scientists do for any other species, helps to understand how ecosystems function. Such transfers are not limited to ordinary biophysically determined boundaries, such as a watershed, but extend far beyond due to the many ways people affect the environment.

To assess people's role in the environment also requires a better understanding of how people perceive the environment and how institutions and traditions are formed to regulate environmental impacts. Research on logging impacts, for example, informs decision-makers about the effects of various logging practices on different ecosystem components, including physical, biological, social, and economic elements. However, this type of information does not describe the acceptability of different or new forms of logging and the institutional mechanisms for such practices, nor transfer the knowledge and technology needed to adopt new logging practices.

Effects of Agency Actions on People

Management actions designed to produce goods and services from the environment, restore forest health, or protect environments and species affect not only natural resources, but people and social systems as well. Agency activities affect the land,

water, air, plants, animals, and other ecosystem components on which people depend and care. Agency activities also influence access to economic opportunity for current and future generations of individuals whose livelihoods are closely linked to public lands and Federal programs. Because the actions of Federal agencies are viewed as major factors that influence their quality of life, Basin residents believe that quality of life should be an important consideration in public land management (Brunson and others 1994).

Agency management activities also affect people who do not live in the Basin. For example, ecosystem conditions influence people who visit the Basin for recreation; people who may visit, work, or live in the Basin in the future; and people who may never visit the Basin but benefit from knowing its resources and opportunities exist and will continue to be there for future generations. These national benefits are substantial, even compared to more direct benefits of Basin resources (see chapter 6, Economic Assessment).

Trust Responsibilities for American Indians

The Basin contains a significant American Indian population, 20 Indian reservations, and one colony (Hanes 1995). Under the provisions of treaties with various tribes, the Federal Government has assumed trust responsibilities for managing natural resources. These responsibilities include ensuring access to, and sufficient quantities of, traditionally used plants and animals. Many of the usual and accustomed locations for traditional uses are on lands administered by the Forest Service (FS) and Bureau of Land Management (BLM).

Because of these various factors, the relationship of public land management activities to treaty and trust responsibilities is a critical component of ecosystem management. This relationship occurs at a government-to-government scale due to the legal status of American Indian tribes. However, the Federal Government and tribal governments often have different definitions of what constitutes trust responsibilities.

Symbolic Values and Meanings

Humans attach meanings to environments. Understanding the biological and physical attributes of resources does not adequately describe the symbolic significance of federally managed resources nor characterize people's attachments to places. "To understand human interactions with their environments, it is crucial to understand human emotional responses to environments and the evolutionary history of those responses" (Parsons and others 1993).

Spiritual and cultural connections to the environment are deeply embedded in American Indian society. The importance of places in the environment in terms of their symbolic value to various cultures also is being recognized (Williams 1995). For example, Old Faithful Geyser in Yellowstone National Park is a powerful symbol in American society; any management and policy that affect the geyser or its viewing access are closely scrutinized. Other places in the Basin may not have such wide national recognition, but have great meaning and importance for local and regional residents. Because these social and cultural meanings are not necessarily related to distinctive spatial attributes (Firey 1945), their inventory and assessment are difficult. However, because ecosystem management ultimately involves management of places, attempting to understand the meanings that people attach to certain places enables managers to make better informed decisions.

Social Assessments Versus Social Impact Assessments

There is sometimes confusion between social assessments and social impact assessments. Social impact assessments are attempts to predict the effects of a specific program (such as a Forest or District plan) or a specific project (such as a dam, campground, or timber harvest) on people and social systems. These assessments are typically conducted by first identifying characteristic baseline social and economic conditions of the area of influence, which is usually a town, county,

group of counties, or group of states, but may include relevant national and global conditions. Next, these assessments describe trends in these conditions. The impact assessment then estimates changes in these conditions or trends that would likely result from either the proposed action or the set of alternatives being assessed.

Although social assessments collect information similar to the baseline data needed to conduct impact assessments, they typically address a broader geographic area and are more in-depth. This chapter assessment, for example, has the mission of describing existing social conditions and interactions with economic, physical, and biological processes.[1]

Social impact assessment has resulted in extensive scientific literature addressing conceptual issues and methodological procedures. Particularly relevant literature includes a recent publication on standards and guidelines (Interorganizational Committee on Standards and Guidelines for Social Impact Assessment 1994), and conceptual discussions such as Burdge (1994), Gramling and Freudenberg (1992), Dietz (1981), Finsterbusch (1985), Finsterbusch and Wolf (1981), and Leistriz and Murdock (1981).

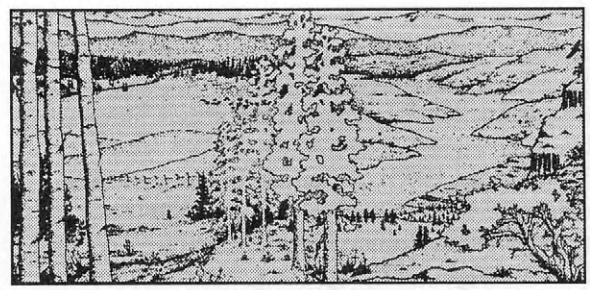
Much of the social impact assessment literature for developing social assessment information databases relates to identifying issues typically of concern to people and procedures. Richardson (1993) provides an example of the link between social assessments and impact assessments. Her report, written in response to concerns about the adequacy of socioeconomic analyses in six draft resource management plan/environmental impact statements released in 1992, was designed to provide more comprehensive and detailed analysis of socioeconomic conditions likely to be affected by BLM management activities in western Oregon.

[1] A separate document, *An Evaluation of EIS Alternatives by the Science Integration Team*, addresses potential social effects of management alternatives described in the draft EISs.

Organization of Social Assessment Chapter

This social assessment is organized into eight topics describing interactions between people and the environment, and the role played by management of FS- and BLM-administered lands. Each topic includes specific conclusions entitled "Implications for Ecosystem Management." The eight topics are:

- A brief overview of settlement patterns in the Basin, with an emphasis on human uses of natural resources and their changes over time. This is provided as historical context to help explain some of the social origins of existing ecosystem conditions.
- The Basin's human population today, trends in population patterns, and projected population growth rates. This information, when considered along with the economic conditions and trends reported in Chapter 6, The Economic Assessment, provides a socioeconomic overview of the existing role of people in Basin ecosystems.
- The relevant attitudes, beliefs, and values of people who care about the Basin's physical, biological, economic, and social components. Ecosystem management, like other land management philosophies and activities, reflects human values. These diverse values and the related attitudes and beliefs regarding natural resources and human uses can be reflected by ecosystem management only to the extent they are articulated and understood.
- American Indians, the longest term residents of the Basin, and their unique status based on numerous treaties, laws, and court decisions. The Federal Government relates to tribes on a government-to-government basis and has trust responsibilities that have not been well defined in the past. Ecosystem management asks for clearer definition and greater incorporation of the needs and concerns of American Indians. Although some of those needs and concerns overlap with broad public issues, many others are unique.



- Existing conditions in small, rural communities in the Basin. Community as a scale or unit of analysis is critical because it has meaning for people. The quality of life in Basin communities and its relationships to management of FS- and BLM-administered lands is one of the major social issues and debates facing ecosystem management.
- Amenities that are based on natural resources, such as scenery and recreation opportunities, and their value to Basin residents and nonresidents. Chapter 6, the Economic Assessment, contains a more detailed description of recreation as a land use and generator of income. Discussion in this social assessment is focused more on the social meaning and benefits of resource-based amenities.
- The role of the public in FS- and BLM-management of public lands. In many ways, people are becoming more involved in decisions that determine which activities take place on public lands. Included are discussions about the various forums for public involvement, the likelihood of reaching stated objectives, and opportunities for public participation.
- An overview of the development and current status of institutions that manage natural resources and are affected by their management. Ecosystem management as a new concept for public land management raises many issues that cross beyond FS- and BLM-administered lands. Many social scientists and members of the public have suggested studying current institutions to assess any needs and likelihoods of their changing to meet challenges posed by ecosystem management.

For the eight topics discussed in this chapter, the scale or unit of analysis varies depending on the issue and data availability. Descriptions of characteristics and processes at the Basin level mask socially important processes and characteristics at the community level. Descriptions of conditions at the community level tend to obscure higher order processes important in understanding social conditions in a broader sense. Data found at one scale may not be available at others, making aggregation or disaggregation inconsistent. Because there was no consistent way to address scale, the discussions occur at the scale considered most appropriate for the topic.

HISTORY OF HUMAN SETTLEMENT AND RESOURCE USE

The following text reviews the history of human occupation in the Basin and some Federal policies that have helped to shape human uses of resources.[2] The main purpose of this discussion is to develop a better understanding of the relationships between settlement patterns and the progression of natural resource use in the Basin. A brief description of land-use practices of American Indians is included, but more details of the relationships between American Indians and Basin resources are presented later in this chapter.

Native American Settlement

The Columbia Basin has been occupied by people for at least 12,000 years, from the time it is believed migration occurred across the Bering Straits land bridge from northern Asia. After continued warming conditions caused glacial retreat, early hunting societies diversified and began fishing and gathering, creating localized cultural groups that followed the seasonal patterns of flora and fauna.

Although the lifeways of native cultures evolved with important regional differences (including distinctive languages), the tribal groups within the Columbia Basin exhibit enough common elements to be considered together. The term "Columbia Plateau culture" is frequently used to differentiate the original inhabitants of the Basin from their neighbors (Beckham 1995).

[2] Much of this discussion is based on Stephen Beckham's report (1995) produced under contract to the ICBEMP.

American Indians were linked to their environment by careful observation, economic calculation, ritual monitoring, and religious explanation. People in the Columbia Plateau culture possessed lifeways and a knowledge of the land gained over centuries of occupation. Specific places for fishing, hunting, and gathering within a yearly rhythm of seasonal rounds became important to tribal groups. Hundreds of native plant and animal species developed cultural importance through subsistence, spiritual, and commercial uses. Favored areas for berry picking, root gathering, hunting, and collecting of other necessary materials offered a familiarity and continuity of use that affirmed people's spiritual beliefs that their lives had been ordered by their "right" behaviors in association with the land.

Access to major rivers was critical. The rivers provided salmon, steelhead, sturgeon, lampreys, suckers, and trout. Methods such as dip-net fishing were especially successful adjacent to major waterfalls of the Columbia River, including Kettle Falls, Priest Rapids, Celilo Falls, Five Mile Rapids, and the Cascades, as well as other rapids on the upper Snake River. Because rivers were arteries for both commerce and food, people resided in permanent villages on terraces adjacent to major streams for most of the year. Family unit structure was based on seasonal harvesting chores. Villages provided a structural coherence among family groups, bringing tribal members together during the winter and early spring to hear the stories of elders and to share in ritual feasts, dances, and renewal (Beckham 1995).

Contrary to the beliefs of non-Indian emigrants arriving in the region in the 19th century, the Basin and adjoining areas were not pristine wildernesses, but ecological systems in which humans had been an active component (MacCleery 1994, Woolfenden 1993). American Indians liberally employed fire as a tool to manage vegetation (Fowler 1986, Robbins 1994). Their fires differed from fires ignited by lightning in terms of seasonality, frequency, and intensity (Lewis 1985).

The low intensity, high frequency fires set by American Indians served many purposes. They were used to enrich grazing; encourage vegetation for browse for large mammals and berries for human and animal consumption; signal other tribes or send warnings; and conduct ceremonies. The widespread use of fires by American Indians over long periods shaped the mosaic of vegetation and the associated animal communities in the West, resulting in an anthropocentric landscape that could only be "natural" to the extent that people are considered a natural part of the ecosystem.

The long-standing patterns of interaction between humans and the land on the Columbia Plateau were disrupted, however, early in the 19th century. In addition to changes in land uses and resulting effects on a broader scale, the introduction of infectious diseases caused population declines in Indian villages of 20 to 50 percent by episode and loosened the cultural fabric of tribal social bands (Boyd and Hyde 1989).

Arrival of Euro-Americans

By 1780, the coastal areas of the Pacific Northwest had been charted by navigators from Russia, England, France, and Spain, yet the Basin remained unexplored by visitors of European origin. Lewis and Clark's expedition from 1804 to 1806 offered Euro-Americans the first glimpse of the potential of the American West: a seemingly endless expanse of land, game, and rivers that attracted adventurers, fur trappers, and homesteaders.

The fur trade soon lured many newcomers. By 1820, 450 vessels had sailed into coastal waters to engage in the fur trade. Fur trappers and traders established outposts throughout the Pacific Northwest in the first decades of the 18th century. The Hudson's Bay Company held a near-monopoly on the fur trade in the Basin. It tried to maintain this dominant position by trapping the fur-bearing animals of the Snake River plains to extinction, discouraging potential competitors.

Missionaries began traveling west in search of converts, bringing not only religion but family-based agriculture, venturing into eastern and western Oregon in the mid-1830s. The success of agricultural operations on the American frontier was a major draw for families (West 1994).

Overland Emigration

The 1840s brought profound change to the American West, as restlessness seized a generation of Americans. Many factors fueled people's desire to seek a new life in the Pacific Northwest. The Panic of 1837 created a prolonged economic recession that hit hard on farmers and land speculators in the Mississippi and Missouri River valleys. Repeated floods in the late 1830s in these same river valleys ruined agricultural production and created infestations of mosquitos that carried malarial fevers. People from Illinois and Missouri were lured by reports of the Willamette valley where neither floods nor pestilence would harm them (Beckham 1995). Another factor was technological expansion; the advent of railroads, steamboats, and communications by telegraph made distant travel and far-flung commerce seem possible. By 1845, Asa Whitney and other investors were already proposing a transcontinental railroad, which was viewed favorably by the Federal Government. A westward movement appeared as practical as it was romantically appealing.

Based on the success of early missions, families began making the nearly 2,000-mile trek on the Oregon Trail from Independence, Missouri, to the Willamette Valley in Oregon. In 1843, 900 people arrived in Oregon in what was called the "Great Migration," followed in 1844 by another 1,200 new settlers.

During the 1840 to 1860 period, most overland migrants passed through the Basin en route to the Willamette Valley's greener pastures and the proximity to navigable waters. Other destinations, particularly California after the gold strike in 1848, lured emigrants away from the Pacific Northwest. To those who had grown accustomed to the lush landscapes of eastern hardwood forests, the Snake River plains seemed too dry, rocky, and forbidding. The Cascade Range has a strong rain-shadow effect in eastern Oregon and Washington with substantial portions of the Basin receiving less than 12 inches of precipitation annually. Even a Federal land donation program between 1850 and 1855 did not entice many settlers to claim land east of the Columbia Gorge.

In this era, a series of Federal laws reflected current policy: to transfer public lands as easily as possible to settlers who could use them. The Congress offered settlers free land through passage of the Homestead Act of 1862. Claimants could receive 160 acres of land for a modest filing fee and proof of five years of residence and improvements. In later congressional acts, including the Desert Land Act of 1877, the Forest Homestead Act of 1906, the Enlarged Homestead Act of 1909, and the Stockraising Homestead Act of 1916, larger size tracts more appropriate for the arid environment were authorized for disposition to settlers.

Passage of the Newlands Reclamation Act in 1902 established the Reclamation Service in the Department of Interior. The Act deposited profits from the sale of western lands into a reclamation fund to support irrigation projects, allowing the Federal Government to underwrite the building of dams, canals, and ditches beyond the capabilities of communities or the private sector. This made it possible for far more people to settle in the Basin.

Not surprisingly, early migrants chose to settle in the environments most likely to sustain them, which were fertile valleys and areas along waterways. In 1860, the Census described just two centers of Euro-American population in the Oregon Country east of the Cascades: The Dalles, Oregon and Walla Walla, Washington, each with about 1,300 inhabitants. At that time, the estimated Euro-American population was just 50,000 in Oregon and 12,000 in Washington, which were great increases from the total of about 13,000 in 1850. From 1860 to 1900, the Euro-American population in Oregon increased to more than 400,000, and in Washington to more than 500,000.

The national survey system established land-use patterns throughout the West. The Ordinance of 1785 ordered the Northwest Territory surveyed into sections measuring one square mile. (At the time, the "Northwest Territory" was the region north and west of the Ohio River, not the Pacific Northwest as the term is used in this document.) Next, the Ordinance of 1787, or the Northwest Ordinance, established a plan of government for the territory that the legislators assumed (incorrectly) would soon be sold and settled. Although modified slightly over the decades, both laws were eventually extended to include lands beyond the Mississippi. These ordinances determined the political form of the growing nation. In 1786, government surveyors laid out a baseline westward from the precise point where the Ohio River left Pennsylvania. They laid the first townships and sections, then built more onto those, range after range, westward to the Pacific. That first square inch of the first surveyor's stake was a polestar of national development (West 1994).

This creation of a national grid system affected the way people thought about land. Presented as squares or rectangles, land can be easily subdivided and turned into a commodity. The shape of land's presentation to an owner dictated styles of farming, allowing each field to be "plowed into straight lines among straight fences besides straight roads" (West 1994).

As in much of the West, settlement and development of the Basin hinged on the use of natural resources and associated economic opportunities. A closer look at the history of mining, transportation and access, grazing, and timber harvest shows the developing interactions between the growing population and the Basin's natural resources.

Mining

Coal deposits had been reported as early as 1833 by an employee of the Hudson's Bay Company, and significant base metal and silver lodes were discovered in eastern Washington during the late 1800s and early 1900s. It was the discovery of gold, however, that attracted many people to the Basin. In 1862, several placer deposits were announced, including deposits on the John Day River near Canyon City, Oregon; at Florence, Idaho, on the Snake River; and at Pierce City and Orofino, Idaho, on the Clearwater River. Strikes in the Boise basin and other locations soon followed. Thousands of miners came to the region, leading to development of towns and their infrastructures, which in turn attracted stock raisers and farmers.

The General Mining Law of 1872, following the precedent of the Mining Law of 1866, opened minerals on public lands to all. Mining practices of the 19th century also established the logic behind western water law: first in time, first in right. Water became a user's property from the moment of its first use until its use was abandoned.

Transportation and Access

The evolution of transportation played a major role in commercial development of the Basin. Public lands were distributed not just to families, but to transportation companies and speculators via auctions in eastern states. Federally supported railroad developments changed the shape of the West. From 1862 to 1871, 61 different land grant subsidies to railroads were offered in the region, the largest to the Northern Pacific Railroad, which eventually secured 39 million acres. The famous "checkerboard" ownership patterns of lands in central Washington state and elsewhere are a legacy of these land grants.

By the 1880s, it was possible to arrive in the Pacific Northwest in five days instead of five months. Commerce and exchange with other regions expanded, establishing patterns of external trade relations that continue to dominate the Northwest's economy. The railroads either "made or broke" a town because a road network of any consequence did not develop until after World War I. Until then, railroads moved cattle, lumber, wool, and other products to major markets.

Railroads allowed more efficient development of base metal and silver districts, compared to initial mining of only the highest grade ores that could be shipped at a profit to distant smelters. Development of communities throughout the Basin followed both the expansion of mining and the extension of the railroad network. Mining towns assumed an urban cast, with hotels, restaurants, general stores, blacksmith shops, sawmills, laundries, and other service businesses that supported workers.

In the early 1900s, road construction began to open entry into the forests of eastern Washington and Oregon. Constructed mainly through river valleys, riparian areas, floodplains, and adjacent hillsides, the roads efficiently provided access but decreased the land's effectiveness as wildlife habitat and provided a new avenue for erosion and discharge of sediment into streams.

In 1916, the region's first paved rural road, the Columbia River Highway, opened to link the western and eastern slopes of the Cascades. The Joint Board on Interstate Highways within the U.S. Department of Agriculture designated a "comprehensive system of through interstate routes," changing previously local initiatives to a coordinated, Federal highway system that remains today. During the interwar years, the miles of hard-surfaced all-weather roads increased in Idaho and Washington by nearly 300 percent and in Oregon by nearly 250 percent. In 1940, the Pacific Northwest had a total of 12,000 miles of roads.

Automobile access provided people with the means to travel throughout the Basin for recreation. In 1916, the National Park Service was created to administer the growing set of national parks and monuments. Although the early parks had been promoted for local economic development, increased visitation and public sentiment to protect natural features led to the Park Service's Organic Act of 1916, mandating a mission of limited development to: "...conserve the scenery and the natural and historic objects and the wild life therein and to provide for the enjoyment of the same in such manner and by such means as will leave them unimpaired for the enjoyment of future generations."

Grazing

Historically, a wide variety of ungulates, including deer, elk, mountain sheep, antelope, and bison, populated eastern Washington and Oregon. Natural predators kept the numbers of ungulates in balance. Because these animals had wide-ranging mobility, their grazing and browsing did not have extensive effects on vegetation. The widespread presence of bunchgrass initially attracted migrant herders who could walk their stock to markets. By the 1870s, ranches and farms were established throughout the Great Basin, Snake River Plains, and Columbia Plateau. The goal of most ranchers was to secure a base of operations with dependable water supplies and the ability to cut and store sufficient hay to feed livestock during the winter; this type of base has sustained many cattle operations to the present day.

Cattle have dominated livestock production throughout the Basin since the first agricultural data collection in the Census of 1870, which reported a total of approximately 76,000 head. Twenty years later, that figure had multiplied over tenfold to approximately 793,000 head. The number of cattle grew steadily throughout the 20th century from 1.4 million in 1910, to 2.6 million in 1950, and to 4.1 million in 1969, a level that has remained relatively constant.

As Euro-American settlement began, not only were many predators displaced, but sheep, and then cattle, were introduced in rapidly increasing numbers. Toward the end of the century, sheep were so numerous on eastern Oregon rangelands that anecdotal reports and photographs suggested summer ranges so laden with sheep that they appeared to be snow drifts. Fescues and other bunchgrasses were irreversibly modified by extensive grazing in the late 1800s and early 1900s. Overgrazing damaged stream and riparian vegetation in many basins in eastern Oregon and Washington. Overgrazing also facilitated the spread of annual cheatgrass and reduced vegetation that had provided fuels for fires. When combined with later fire suppression efforts, the result was reduction of an important ecosystem disturbance.

In the 1920s, ranchers and others recognized that overgrazing of public lands, in combination with drought conditions, was severely impairing the land's ability to support their operations. Impetus for initial regulations also came from Frederic V. Coville's influential *Forest Growth and Sheep Grazing in the Cascade Mountains of Oregon,* published in 1898. His recommendations led to an allocation and permit system in which stockraisers secured grazing rights within bounds of regulations established by the Forest Service.

The Taylor Grazing Act of 1934 brought range regulation to 142 million acres in 11 western states, removing the land from potential sale and placing it under the jurisdiction of the Grazing Service, which evolved into the Bureau of Land Management in 1946. Range improvement projects were undertaken and local advisory boards established to allocate and manage the rangelands. The condition of rangelands in the Basin has generally improved since then, with the exception of riparian areas, which have continued to decline in much of the Basin.

Timber Harvest

Vast stands of timber on the eastern slopes of the Cascades and in the Bitterroots and Rockies were another resource subject to increasing demand. Following on the heels of mining and agriculture, a third leg of the Basin's economy, the timber industry, took off near the close of the 19th century. The industry paralleled development of mines and railroads; railroads needed wood for ties and trestles, mines needed timbers for shoring, and lumber mills needed access to the woods to extract logs.

Serving only local markets in the early years after settlement, the industry began to change with completion of the Northern Pacific Railroad in 1883 and the advance of the Oregon Railway and Navigation Company's line eastward to the Blue Mountains and southeast via the Oregon Short Line to connect with the Central Pacific. Their construction created an important market for ties, trestle materials, and finished lumber for warehouses, depots, and dwellings for workers.

The influx of settlers engaged in farming created local markets for forest products. Spokane, Washington became one of the important regional manufacturing centers that met these needs. In 1888, the Spokane Mill Company produced 15 million board feet of lumber, 6,000 doors, and 10,000 windows. The following year, Spokane had nine mills that cut an estimated 30 million board feet of lumber valued at $2.2 million. Loggers supplied these plants with timber transported down the St. Joe, St. Maries, and Coeur d'Alene rivers and then rafted across Lake Coeur d'Alene.

By the end of the 1880s, mills in the Blue Mountains of Oregon were harvesting up to 30 million board feet annually, and the Clearwater River in Idaho was reported as a "floating woodyard." By 1900, exhaustion of the supply of trees in the upper Midwest invited timber investors to look westward, and the northern Basin became the focus of a new scramble for wood supplies. The rapid increase in harvest levels was reflected in Idaho, where 65 million board feet of lumber was cut in 1899. By 1910, Idaho was producing 745 million board feet, and its market had shifted from local to national. The railroads enabled mill owners to supply and compete favorably in the Dakotas, Nebraska, Wisconsin, Iowa, Colorado, and other states. Employment data in the logging and lumbering industry for Idaho shows the growth of those enterprises in the early 20th century. In Idaho, for example, employment of loggers, rafters, and sawmill workers increased from just over 300 in 1880, to more than 8,000 in 1920, and to 14,900 in 1995.

Because smaller stems could not be processed efficiently, early harvesting concentrated on the largest trees of the more important commercial species, such as ponderosa pine and western larch. Eastern markets in particular demonstrated a preference for ponderosa and Idaho white pine, leading to select cutting where other species in mixed forests were left standing.

The Forest Service was established in 1905 to conserve water, as well as to manage a growing inventory of Federal forest reservations that dated to 1891. Theodore Roosevelt entered office in 1901 with 41 million acres in reserves; when he left office in 1909, there were 151 million acres of national forests whose management was to ensure a sustained yield of timber to contribute to national growth and the stability of local economies. In the view of Gifford Pinchot, the first Forest Service Chief, the forests could protect water supplies for irrigation and western cities, provide cheap grazing, and repay the Federal treasury with timber sales. After nearly a century of policies to dispose of public lands, the Federal Government started to view the remaining public domain as a storehouse to sustain productive values. The Progressive Movement influenced leaders in government to emphasize "scientific" management of physical resources for more "efficient" development.

Exclusion of fire from ecosystems began systematically in the early 1900s; fire was viewed as a threat to forests, as well as to the lives and property of increasing numbers of settlers. The newly created Forest Service, unaware of the increased problems

with wildfire control and forest health, believed that fires killed regeneration under larger trees. This societal attitude prevailed until fairly recently as fire's natural role as a disturbance came to be more widely understood. While fire was being used west of the Cascades to reduce slash after logging, fire was being excluded from the east side of the Cascades where it historically had occurred more frequently. Although well intended, this management philosophy over time resulted in changing forest stands from seral fire-adapted species, to species that are more susceptible to fire and that tend to form unhealthy stands more prone to larger-scale fires, as well as increased outbreaks of insects and disease.

Growth of the timber industry continued in subsequent decades, driven by demand for wood products in growing urban centers, especially in the Midwest and California. Development of the skidder, caterpillar tractor, log truck, and chain saw lowered costs, increasing production dramatically. The easier terrain of eastern Oregon and Washington facilitated the change to more mechanized equipment. Timber cutting practices were adapted to fit the technology available, leading to clearcutting.

From 1945 to 1970, timber harvest on Federal lands in the Basin increased about 5 percent per year, or 50 percent faster than the growth of the national economy. This increase was important to the expansion of softwood and plywood production in the western states, which supported many communities. Nationwide, harvest volume increased from 4 billion board feet in 1950, to 11.4 billion board feet in 1970, 90 percent of which came from western national forests, and 41 percent from Washington and Oregon.

Fishing and Dam Construction

When Euro-American settlers arrived during the early 1800s, salmon were abundant and diverse. Spawning runs of chinook salmon made their way up the mainstream Columbia to the Snake River, and on up to the headwaters of the Owyhee and Bruneau rivers and Salmon Falls Creek as far as Nevada.

Estimated historical run size for all species of salmon and steelhead in the Columbia River ranged from 10 to 16 million adult fish. Not only was their course unimpeded by dams, but there was ample suitable habitat to support these populations. Fur trappers and traders reported extensive stands of willows and alders growing side-by-side across many of the valleys and along moist gulches and draws; they also reported wide, wet meadows along stream systems throughout the Basin. The Ochoco Mountains take their name from an American Indian word meaning "streams lined with willows."

Commercial harvest began in earnest when the first cannery started operating on the Columbia in 1866 and soon exceeded sustainable levels. Commercial catches of chinook salmon in the Columbia peaked in 1883 when about 43 million pounds of fish were landed. Coho, sockeye, chum, and steelhead also were abundant in the Basin. Catch of coho peaked at 6.8 million pounds in 1895, and catch of sockeye and steelhead totaled 4.5 million pounds.

By the late 1800s, overfishing was blamed for broad declines in chinook salmon runs. By 1900, certain fishing gear was banned to protect spawning runs but impacts from mining, timber harvest, livestock grazing, and agriculture had begun.

New Deal[3] programs were critical in sustaining and building infrastructure in the Basin. Perhaps the most publicized Federal programs were the dam projects along the Columbia and Snake rivers. The Army Corps of Engineers had been involved in surveys, navigation, and flood control along the Columbia River since the 19th century, but these activities were of low intensity compared to the major dams constructed during the Depression[4] and after World War II on the Columbia River. In 1938, Bonneville Dam became the first dam on the Columbia, and the Grand Coulee Dam was built in 1942.

[3] Policies and programs for economic recovery and reform, relief, and social security introduced during 1930s by President Franklin D. Roosevelt and his administration.

[4] Period of severe economic hardship in early 1930s.

Although the Federal initiatives from the New Deal did not extend to regional planning, such as in the Tennessee Valley, the effect of Federal actions in the Depression years pulled the region out of the frontier and onto the main stage of late 20th century development. As Abbott (1994) wrote:

> *Whether residents liked to admit it or not, the federal initiatives saved the West from collapse. There were fewer farmers and miners in 1940 than in 1920, and there were more abandoned towns on the high plains and plateaus. By and large, however, the West in 1940 had new resources in place for an economic take-off: new electric power, new expertise in large-scale construction, workers with new skills for an industrial economy, and a renewed commitment to the progressive agenda of efficient resource development.*

A broad public consensus on construction of the dams helped the Nation out of economic crisis, even though biologists recognized at the time that dams would likely be barriers to native salmon runs. Later, however, the debate over dams symbolized new types of emerging social values. After World War II, as more citizens became affected by environmental changes, grassroots action and citizen demands began to bring to the forefront other values that were deemed environmental. This citizen movement set the course for conflict between forces associated with large-scale management and technology and those emphasizing protection of environmental quality. This change was symbolized by debate over dams in Hells Canyon, which shifted from who should build them and how many to the possibility, voiced by Supreme Court Justice William O. Douglas, that maybe the river had greater value in its free-flowing condition.

Another landmark decision regarding social priorities for fish resources came in 1974, which marked the beginning of a key set of court decisions with a *United States v. Washington District Court* decision reaffirming the priority of off-reservation fishing rights. Tribes were allowed up to a 50 percent share of harvestable fish returning to accustomed traditional fishing sites. More detail on laws specific to American Indians is provided later in this chapter.

Recent Legal and Political Climate[5]

Social discussion regarding land uses described above has been reflected in a series of laws, policies, and court decisions. A brief history of some of these social actions helps to provide context for understanding current debates about ecosystem management.

Since passage of the Multiple-Use Sustained-Yield Act of 1960, the Forest Service and Bureau of Land Management have had increasingly complex and conflicting demands on Federal land stewardship, with policy dictating that multiple demands be met from a limited resource base. In the late 1950s, the Forest Service experienced difficulties with ambiguities of its Organic Act mandates and subsequently evolving responsibilities. Wilderness enthusiasts and others sought to put recreation on an equal footing with other uses. The traditional users, which were timber operators, ranchers, and miners, argued for greater allocation to their particular needs, causing the Forest Service to seek legislative clarity from the Congress (Coggins and Wilkinson 1981).

The result was the Multiple-Use Sustained-Yield Act of 1960 (MUSYA) which defined multiple use as "management of all the various renewable surface resources of the National Forests so that they are utilized in the combination that will best meet the needs of the American people...without impairment of the productivity of the land, with consideration being given to the relative values of the various resources, and not necessarily the combination of uses that will give the greatest dollar return or the greatest unit output."

The Multiple-Use Sustained-Yield Act has meant all things to all people. The literature on the meaning and application of multiple-use sustained-yield management has burgeoned with-

[5] The initial draft of this section was written by Christopher E. DeForest and Amy L. Horne. Horne is an economist at the USDA Forest Service, Pacific Northwest Research Station; DeForest is an independent contractor.

out appreciably clarifying the concept as a legal standard (Coggins and Wilkinson 1981). The Act could have marked a clear continuation of emphasis on commodity production. It could also have stated what weight to give to society's different demands on the land. Instead, it institutionalized uncertainty and ambiguity, and marked the beginning of the modern period of conflict over what constitutes proper stewardship of the public lands.

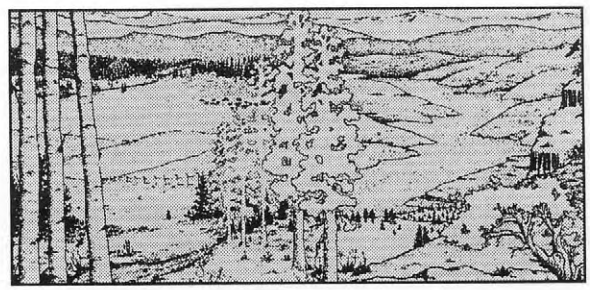
The 1970s have been called the decade of "Regulating Public Lands" (Caldwell and others 1994). In 1975, a Federal court enjoined timber sales on the Monongahela National Forest in West Virginia, finding the Forest Service in violation of the 1897 Organic Act. The Forest Service complied with the court order to develop a new multiple-use plan and to limit the size and range of clearcuts, extending these policies to all National Forests.

The Forest and Rangeland Renewable Resources Planning Act (RPA) of 1974 was intended to institute long-term strategic planning in the Federal Government (Cubbage and others 1993). In the name of multiple use, the Forest Service assembled plans to manage all resources in an attempt to diffuse arguments that the agency concentrated on timber at the expense of other outputs. However, congressional failure to allocate the necessary funding resulted in maintaining the status quo of primarily focusing on timber (Cubbage and others 1993).

Senator Frank Church of Idaho chaired congressional hearings in 1972 that culminated in a report recommending major restrictions on the size and suitability of clearcuts; the Church Report was instrumental in the development of the National Forest Management Act of 1976 (NFMA), an amendment to the RPA. The Federal Land Policy and Management Act of 1976 (FLPMA) gave the Bureau of Land Management a multiple-use mandate similar to the Forest Service's in MUSYA and requirements for comprehensive long-range planning similar to those in NFMA (Cubbage and others 1993).

The 1980s were characterized as a decade of "Clashing Imperatives" (Caldwell and others 1994). There was bitter debate about Northwest old growth among the Congress, several administrations, and the courts, in which the spotted owl was used as legal leverage to redefine desirable management of the national forests. The polarities were seen as protecting ecosystems by protecting endangered species, versus maintaining local timber-dependent economies. The decade included Judge Dwyer's rejection of the 1986 Forest Service spotted owl management guidelines,[6] which enjoined timber sales pending revisions to the guidelines. Then, there was a 1989 congressional rider to undo the injunctions for two years; subsequent scientific reports on old growth, spotted owls, timber, and tradeoffs; and the Supplementary Environmental Impact Statement (EIS) and Forest Ecosystem Management Assessment Team report (FEMAT 1993). A new approach to reserving old-growth ecosystems (Option 9 of the Northwest Forest Plan) was adopted but has been under almost continuous challenge.

The 1990s are being characterized by continued controversy and public concern about ecosystem health and its physical, biological, economic, and social meanings. The costs and benefits of programs for activities, such as salvage logging and its appropriate role, have become national issues. The aggressive fire suppression policy of Federal land-managing agencies has been increasingly criticized as agency and academic foresters learned more about natural fire cycles (Langston 1994, Everett and others 1994). The health of forest, rangeland, and aquatic systems is under close public scrutiny, as are the tradeoffs associated with achieving various levels of health at various places in the Basin. Recent debate over reform of Federal rangeland management demonstrates the social and political intensity of rangeland, as well as forest, issues. It remains to be seen whether ecosystem management will be viewed as the solution to these complex issues.



[6] *Seattle Audubon Society* v. *Evans*, 771 F. Supp. 1081 (W.D. Wash) 1991.

Implications for Ecosystem Management

A brief look at the history of interactions between people and other ecosystem components of the Basin provides some explanation for past actions. Besides explaining how present ecosystem conditions evolved, this discussion also provides rationale for human uses of natural resources and the basis for people's judgements about the acceptance of those uses and their effects. Several lessons emerge from study of the history of people's interactions with physical and biological resources in the Basin:

- People's perceptions of Basin resources have changed dramatically in a relatively short time. Initially viewed by Euro-American settlers as unpriced, seemingly limitless supplies to be disposed of efficiently, many natural resources are now increasingly scarce and subject to highly competitive uses. Federal laws and policies regarding resource use reflect the changes in both the supply of resources and public perceptions of their values.
- Although the industries that led to settlement and infrastructure development of the Basin (mining, timber, ranching, and transportation) still play critical roles in the social and economic functioning of Basin ecosystems, their roles have changed with time and the tremendous growth of new industries.
- Landscape ecology analyses suggest that even if society wanted a return to pre-European settlement conditions, it would not be possible to achieve. The question now is: "What does society want to accomplish through ownership and management of BLM- and FS-administered lands?"

POPULATION AND DEMOGRAPHIC CHARACTERISTICS

Management of Federal lands in the Basin occurs within a context of the human population, its size and growth, and other demographic characteristics. The following text describes current human populations, reviews recent and projected patterns of population growth, and discusses lifestyles of the rural population in the Basin. When considered in conjunction with economic trends described in the Economic Assessment, including poverty, unemployment, and other economic measures that have obvious social implications, this information gives land managers and other decision-makers an idea of demands likely to be placed on natural resources. Detailed demographic characteristics are provided in a supplemental report (McGinnis and Christensen 1996).

Population Dynamics and Characteristics

The Basin is sparsely populated, with a density of about 11 people per square mile compared to the national average of 70. Although the counties in the Basin account for about 8 percent of the land area in the United States, they have only 1.2 percent of the Nation's population.

The total 1990 population in the Basin was just less than three million people (USDC 1991a and b). Washington residents comprise 38 percent of the Basin's population, compared to 27 percent for southern Idaho, 12 percent for Oregon, 11 percent for Montana, 7 percent for northern Idaho, and 5 percent for the other states (Wyoming, Utah, and Nevada). The most populated county is Spokane in Washington, which has approximately 361,000 people. Nearly half of the population is located in 12 of the Basin's 100 counties, although just 6 of these (Ada and Canyon in Idaho; and Benton, Yakima, Franklin, and Spokane in Washington) are large enough to be called metropolitan counties.

The age distribution of Basin residents is similar to that of the Nation, but the Basin has a greater proportion of people younger than age 18 and a smaller proportion in the prime wage-earning years of 25 to 49 (McGinnis and Christensen 1996). Between 1980 and 1990, the age structure of Basin residents changed significantly. The 65-and-older age group increased by a greater proportion (28%) than other age groups, and the 18-to-24 age group declined by 20 percent. This proportion reflects in-migration rates and the aging of the baby boomers.

The Basin has a larger proportion of Whites (92%) and American Indians (2.5%) than the Nation as a whole (80% and 0.8%, respectively), and a smaller proportion of Blacks (0.6% compared with 12% nationally). The Basin also has a smaller proportion of Hispanics (6.7% compared with 9% nationally), although Hispanics are the largest non-Anglo group in the Basin. From 1980 to 1990, the Hispanic population increased by 69 percent.

Ethnic minorities who have come to the Basin use public lands for income and recreation. Many minorities were drawn to the Basin by jobs in irrigated agriculture. Few of the significant numbers of minorities who arrived in the Basin in the 1940s settled permanently. Many spoke only Spanish, lived lifestyles confined to camps, worked long hours during harvest season, and returned to their homeland when the crop season ended. Few had opportunity to realize or discover the Basin's recreational possibilities (Valle 1994). Some migrant workers who journeyed with their families began to settle in the Basin in the 1950s and 1960s (Gamboa 1990). Increasing numbers of single workers began to come from Mexico in the 1970s, first from northern and central Mexico and lately from southern Mexico. Some of these also settled in the Basin.

As children of the first migrant settlers have attended school, learned English, and entered jobs outside of agriculture, their available time has increased. Recreation has become more important. Although family outings to nearby parks constitute some of this recreation, increasing numbers of this population segment hunt, fish, and camp on public lands. Although the numbers using public lands are proportionately low for their population, increasingly more are expected as more of the first and second generation work outside agriculture (Pfister 1993).

Public lands are used by large numbers of minorities who earn income in forestry-related activities, including reforesting, pruning, and thinning trees (Hansis 1995). Migrant workers and southeast Asians harvest special forest products, such as huckleberries, beargrass, and mushrooms. Other products, such as medicinal plants, may become the next commodity of interest for Southeast Asians. Besides providing income, some harvesting may be a basis for family and social cohesion. In some cases, entire families go to public lands, camp, pick beargrass and mushrooms, and socialize in extended kin networks.

The Basin contains or overlaps 20 American Indian Reservations and one Colony, which includes some trust lands; these areas total about 14,000 square miles or 5 percent of the Basin. In six counties, reservation and trust lands account for more than 40 percent of the land base. In 1990, about 115,000 people lived within the borders of these lands. Hanes (1995) contains a list of Indian tribal governments having interests in the region.

Nearly two-thirds of the Basin's population live in towns, villages, and cities. The Bureau of Census recognizes 400 incorporated places and 76 "Census Designated Places," which are locations that are unincorporated but have an identity to the local population. Although 65 percent of the Basin's population (as recorded in the 1990 Census) live in a town, village or city, most of these communities are relatively small. Only about 30 of these communities have more than 10,000 population; most have less than 2,500 people. Additional detail about the Basin's small, rural communities is included later in the section on community resiliency.

Population Trends

Concerns about the effects of rapid growth in the rural West have been widespread in the media. Although people in rural communities desire economic opportunities that are associated with population growth, they are concerned about social and environmental consequences and the ability of communities to cope with a new "Rocky Mountain resurgence." What is clear from recent growth statistics and media discussions is that such rapid growth brings various impacts. This is an issue not only for local governments, but also for managers of adjacent Federal lands.

To understand how the Basin's population has changed in the past and may change in the future requires understanding the two major components of population change, which are natural increase and net migration. Natural increase is the number of deaths subtracted from the number of births in

a year; this indicates if an area's population is increasing or decreasing as a result of shifts in fertility or mortality. For many rural areas, natural increase has been negative, paralleling national trends for the past few decades.

Net migration is the difference between out-migration and in-migration. The sum of these two components shows changes in the population base; a negative figure indicates that more people are moving out of an area than are moving into it. There have been two major trends in migration patterns in the United States since 1900: (1) migration to the western and southern states, and (2) migration from rural to urban areas. The West as a whole has gained population through migration.

The Basin's demographic patterns have followed national trends over the past 45 years. Figure 7.1 shows the population of 100 counties in the Basin by decade. During the first two decades of this period, 1950 to 1970, there was a significant national level out-migration from rural to urban settings. This pattern was also reflected in the Basin, where over one-third of the counties showed population losses in this period.

During the 1970s, the second trend changed significantly (Fuguitt and others 1989). During this time, most counties in the Basin reported population increases, reflecting the "rural renaissance" occurring for the Nation as a whole in that decade. Brown and Beale (1981) regard the population turnaround of the 1970s as "one of the most significant demographic events of recent decades." The 1980s demonstrated a return to traditional migration and population patterns (Johnson 1993), as 41 percent of the counties in the Basin showed population declines.

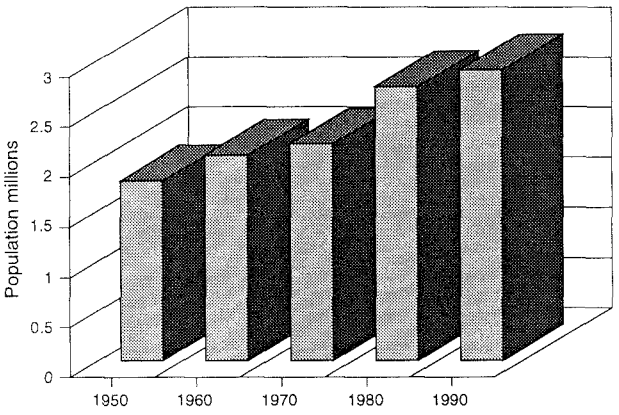


Figure 7.1 - Population of the Basin by decade.

However, in the early 1990s, another urban-to-rural migration began. Johnson and Beale (1994) report that nationally about 43 percent of the population growth in nonmetropolitan counties between 1990 and 1992 was due to migration. Census data for the Basin shows that an even higher proportion (64%) of the net population increase from 1990 to 1994 could be attributed to migration. Nationally, counties that attract retirees or are "centers of recreation" were more likely to gain population, and 82 percent had net migration in the 1990 to 1992 period. In the Basin, 96 percent of the counties increased in population for the period 1990 to 1994, reversing the trend of the 1980s (Johnson and Beale 1994). Map 7.1 shows population growth by county for the 1990 to 1994 period. The absolute increase in population in this four-year period is equal to one-third the increase occurring in the previous three decades.

The impact of in-migration differs among counties. One type of county that showed large increases was "recreation counties," which are counties in which recreation and tourism play a major role in the economy (Johnson and Beale 1994). In recreation counties, about 77 percent of the population growth could be attributed to net migration. The figures for metropolitan and other rural counties were 60 and 57 percent respectively. Recreation counties are particularly important centers of growth in the Basin; although recreation counties accounted for 17 percent of the population in 1990, they accounted for 24 percent of the total population increase in the Basin and 29 percent of the total net migration.

Map 7.1 - Change in percent of population by county, 1990-1994.

Although most communities and counties are growing, some traditionally agricultural counties are experiencing population declines, principally because of rising production efficiency in agriculture. Counties distant from metropolitan areas also have generally experienced slower growth or population decline.

Projected Population Growth

There are several reasons for considering future human population growth. First, population is a significant component in understanding the context within which ecosystem management decisions will occur. Second, demands of human populations for both commodities and amenities associated with natural resources on Federal lands are partly functions of population levels. Third, the additional development resulting from population increases escalates the potential for habitat fragmentation, particularly in popular "recreation" counties located in ecologically diverse settings. Finally, although development occurs on private lands, people also affect nearby Federal lands, so population change suggests a need for appropriate Federal and local cooperation.

This assessment compares two projections of potential population growth in the region, each based on its own set of assumptions, especially specific to net migration (fig. 7.2). The first, and lower, population projection was developed by the Bureau of Economic Analysis (BEA) in 1994; it is strongly influenced by projected economic conditions and patterns of population growth that occurred in recent periods. However, BEA projections are below the current population for many counties in the Basin, suggesting the need for an alternative projection based on new assumptions.

The second, and higher, population projection was made by ICBEMP staff (McCool and Haynes 1995). They based their assumptions about a natural increase on persistent differences between the Basin and the Nation, with the Basin averaging about 22 percent higher. Their projection also assumed a rate of net migration from the years

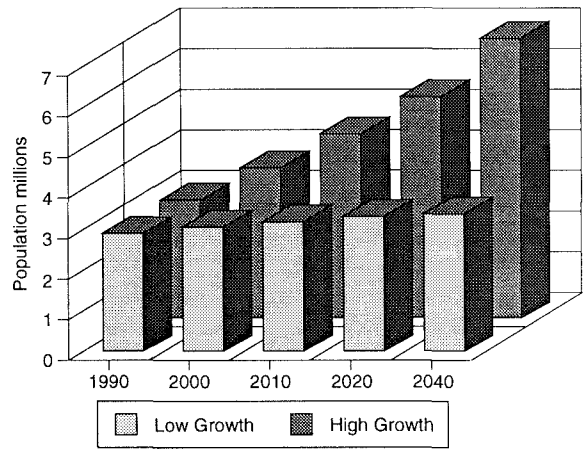

Figure 7.2 - Estimated Basin population by decade using two different projection assumptions.

1995-2000 equal to the 1990-1994 rate, and then a reduced rate to zero by the year 2030. Another assumption of this projection was that recreation and metropolitan counties in the region would record higher growth rates than other counties.

Both projections were developed for counties, and then aggregated to the 100-county Basin level. Beginning in 2010, the projections depart dramatically. Although uncertain and subject to alteration by many factors, both projections call attention to likely demands on resources, potential conflicts, and growth management issues. Although the high projection results in what could only be termed spectacular population growth, the overall population density within the Basin would remain well below the national average. This population would be concentrated on private lands, which compose 48 percent of the Basin's total area.

Migration

Migration is an issue for several reasons. The low population growth estimate cited above assumes, for all practical purposes, no net migration into the Basin; in the higher estimate, migration forms the bulk of the population increase. People's reasons for migrating can be affected by public land

management policies and actions. Knowing the reasons for migration can help managers to better understand the potential of individual areas for in-migration and to become active in mitigating effects on Federal lands.

The Basin's overall growth in opportunities for employment, as discussed in the Economic Assessment chapter, continues to be a central factor in people's decisions to relocate. In addition, recent literature shows that migration decisions often contained not just economic dimensions such as employment opportunities, but noneconomic dimensions such as amenities or family ties (Wardwell 1992). The migration literature traditionally was principally concerned with economic motives, such as moving for a new job or a job transfer. Census enumerators did not ask people about quality of life or lifestyle factors as motivations for relocation. Wardwell (1992) argued that research demonstrated the economic explanations were insufficient to explain the return to rural areas during the 1970s, although increases in communication and transportation technology made rural areas more feasible as bases of operation.

Only since the "rural renaissance" of the 1970s have scientists explored non-economic reasons for migration (Zuiches 1980, 1981). Long (1988) reported that about 50 percent of the households moving between states in the 1979 to 1981 period relocated mainly for other than work-related reasons:

> *A case can be made that a great many moves are not accounted for by classic economic approaches linking long-distance migration to employment opportunities... Many of the 10.1 percent of moves that could not be classified in one of the 34 preset categories may have represented persons seeking lifestyles and values that do not appear to be governed strictly by economic considerations.*

Between 1979 and 1981, motivations for migration were strongly related to age (Long 1988). Job-related motives were most frequently cited by younger movers, while older movers listed climate and family among other reasons. As the regional and U.S. population ages, these latter motives will have a greater influence on the population. Areas high in amenities attractive to seniors will experience higher than average population growth. Lifestyles of these individuals may be more oriented toward outdoor recreation and protection of natural resources. The 20 counties classified as "recreation" counties in the assessment area already have a different lifestyle composition than other counties in the region, as discussed in following text.

The economic impact of retirement can be substantial; population, employment, and personal income increased significantly faster over the period 1969 to 1989 in rural counties classified as retirement counties than in other rural counties (Deller 1995). Besides being higher as a source of personal income than for the Nation as a whole, transfer payments within the Basin have increased much faster than the national average (see discussion on communities in this chapter and also in the Economic Assessment, Chapter 6).

Population Lifestyles

A description of Basin population characteristics relevant to ecosystem management would be incomplete without an overview of Basin lifestyles. The character of rural life in the Basin varies as much as the people do, and the Basin population is diverse in many ways. Although describing Basin lifestyles at this broad scale oversimplifies the many ways that people live and earn a living in the Basin, there are some advantages, such as being able to compare Basin lifestyles with those elsewhere. Not surprisingly, many Basin lifestyles are tied closely to the natural environment and to public land management.

To better understand lifestyles within the Basin, the ICBEMP used a lifestyle segmentation system called PRIZM developed by Claritas (1994). PRIZM describes people's lifestyles through multivariate analysis of household characteristics combined with consumer purchasing behaviors. The two primary criteria defining lifestyles are affluence and residence (urban to rural). The database

describes 62 lifestyles located in 12 major groups, each representing about 1.5 percent of the Nation's households. Not all 62 lifestyles are represented in the Basin, because several exist only in large cities or have strong regional affinities.

Twelve lifestyles tend to be found in rural areas or small communities in the Basin (table 7.1). These lifestyles are most subject to change as the population grows and as the underlying economic structure of communities shifts. Certain rural-based lifestyles are found more frequently in the Basin, and their distribution is much different from the west side of the Cascades. Rural-based lifestyles account for more than 50 percent of the Basin's population, compared to about 20 percent of the population nationally or west of the Cascades.

The Basin is dominated in rural areas by agriculturally based lifestyles. However, in rural counties where rapid population growth is occurring, Basin lifestyles differ significantly from other areas. In general, compared to households nationally or those west of the Cascades, lifestyles in the Basin's rural areas experiencing rapid growth appear more oriented toward the natural environment, with occupations related to natural resources, and recreation activities dependent on resources from Federal lands. The importance of environmentally based amenities to Basin lifestyles is discussed in more detail later in the chapter addressing social benefits of amenities.

Implications for Ecosystem Management

Besides being helpful to ecosystem managers for decision-making, information on population and lifestyle changes results in significant and often controversial discussions about the future of communities and Federal lands within the Basin. Even assuming modest in-migration, the level and characteristics of the population will affect any such debates and lead to additional demands on public lands and resources within the Basin.

Rapid population growth in the Basin presents major challenges to the BLM and FS, especially in locations having high levels of environmental amenities. In these areas, growth and associated development threaten the qualities that make such places attractive for recreation, retirement, and new businesses. At the urban-wildland interface, where such growth is most dramatic and developments are most visible, habitat fragmentation and fire protection are critical issues. Habitat loss on private lands translates into increased pressure on remaining habitat on Federal lands, further exacerbating constraints on natural resource commodity production. Increased numbers of residential dwellings adjacent to forest and rangelands present new challenges in fire prevention and suppression for Federal and local agencies.

Johnson and Beale (1995) showed that counties with either rapidly increasing or declining populations tend to have more difficulties raising revenues for needed services. Although the amenities on Federal lands are sources of economic growth, they indirectly present problems in planning and managing growth by stretching the response capacity of local governments to develop and implement solutions. Changes in Federal revenue resulting from policy changes may exacerbate such local capacity.

The important conclusion from lifestyle data is that lifestyles vary significantly within the Basin, and also differ from those experienced elsewhere. Management actions affecting Federal lands differentially affect people across the Basin based on the distribution of lifestyles at specific locations. In addition, the ability of agencies to meet demands for outdoor recreation may vary according to population growth and lifestyle composition. Population growth and changes in lifestyles distribution also suggest a rethinking about vegetation management alternatives and their potential to affect people with varying lifestyles. For example, rapidly growing rural areas generally attract people whose lifestyles suggest sensitivity to environmental modification.

Table 7.1—Rural-based lifestyles in the Basin.

Lifestyle Segment Label	Definition
Small Town, Blue-Collar Families	Moderately-affluent people living in mid-scale, low-density towns located at outskirts of larger cities. Tend to be skilled workers in industrial and blue-collar occupations, primarily mining, milling, manufacturing, and construction. Very outdoor oriented.
Mid-scale Families and Farmland	Have average college education and income levels well above U.S. median. Well-paid, skilled craftsmen, machinists, and builders, living in scenic locales. Family-centered; devoted to hobbies, hunting, and boating.
Rural White- and Blue-Collar Farm Families	Only rural segment with above average college educations. Has even mix of white- and blue-collar jobs and high index for personal computers, reflecting several new, hi-tech industries in pristine, ecological sanctuaries.
Middle-Class Rural Families	Blue-collar occupations. Live in wide variety of agricultural settings.
Rural Blue-Collar Workers and Families	Least affluent of rural clusters. Consist of large proportion of blue-collar workers, mostly married with children. Bowl, hunt, sew, and attend auto races.
Retirement Town Seniors	Found over wide range in country. Includes myriad of rustic towns and villages in scenic areas where seniors choose to retire. Younger and less urban and affluent than other retirees. A few play golf, but most prefer to adopt local customs.
Older Families, Mine and Mill Towns	Tends to have very low incomes; ranked 56th out of 62 segments. Older, largely single, with fewer children. Towns are located in scenic areas.
Rural Farm-Town and Ranch Families	Includes farming, forestry, fishing, ranching, mining, and other rural occupations. Close to median income level, large families, and like fishing.
Farm Owners and Tenants	Centered in Great Plains, but has large representation in the Basin as well. Primarily owners and tenants of farms; not very wealthy. Hgher than average proportion of Latino migrant workers.
Moderate Blue-Collar/Farm Families	Tends to be in more isolated areas. Low income, with large families. Prefer hunting, fishing, and camping.
Low-Income, Older, Rural Couples	Third most elderly segment in nation. Have relatively-low incomes, but preference for country clubs, power boats, and sailboats. Oriented around rural environments.
Poor Isolated Areas With Older Families	One of lowest income segments in the Basin. Rural lifestyle; primarily blue-collar occupations.

ATTITUDES, BELIEFS, AND VALUES TOWARD NATURAL RESOURCES AND PUBLIC LAND MANAGEMENT

A Framework for Ecosystem Management in the Interior Columbia Basin and Portions of the Klamath and Great Basins (Haynes and others 1996) states that a main feature of an ecosystem approach to managing natural resources is to include people, their values, and activities. The *Framework* acknowledges that people may make demands on ecosystems that exceed physical and biological capabilities in the long term. Developing and implementing an ecosystem management plan requires knowledge of the type and quantity of human demands for ecosystem products and the human values associated with these expectations.

The Forest Service's National Human Dimensions of Ecosystem Management Task Force concluded: "The human dimension of ecosystem management must include information about people's traditional and changing perceptions, beliefs, attitudes, behaviors, needs, and values and the past, present, and possible future influences of humans on ecosystems." The ICBEMP Charter reflects this thought by referring to consideration of sustained long-term economic, social, and ecological values of the region and issues identified in scoping. In addition, one of the ICBEMP's key policy questions (November 8, 1994) addressed the impact of ecosystem management on major social issues by requiring an understanding of local, regional, and national attitudes, beliefs, and values associated with natural resources and public land management.

Because ecosystem management is a human construct, like multiple-use management or other public land management systems or philosophies, the decisions on whether and how to implement it are made in a political arena. The desirability of different alternatives is a decision normally determined with public input to reflect the values of the groups involved in the debate over a preferred alternative. Knowledge of prevailing social attitudes relevant to ecosystem management provides a basis for evaluating social acceptability and developing appropriate mitigation. Existing laws, regulations, and policies reflect prevailing social views, but may not adequately describe public sentiments regarding current issues. Finally, surveys that sample populations of interest, such as the Nation's population-at-large or Basin residents, provide a context for interpreting frequently expressed demands of special interest groups.

Attitudes, Beliefs, and Values

The historical overview presented early in this chapter described social mind-sets regarding the role of humans in ecosystems and changing perceptions over time. The following text provides more detail on the current wide range of attitudes people hold toward natural resources and public land management. The objective is to create a more complete understanding of these attitudes, as well as people's expectations for implementing ecosystem management. Several research efforts

have helped identify people's various values, beliefs, and attitudes toward natural resources, the environment, and the agencies that manage land for the public.[7]

Because the terms "attitudes, beliefs, and values" have been used differently by social scientists, definitions are provided before presenting the research. The purpose is not to suggest what definitions are best nor to redefine the terms, but to provide descriptions and examples that lead to common expectations in the presented text.

Attitudes

Attitudes reflect people's evaluations of something as favorable or unfavorable. Although definitions and methods of measuring attitudes vary widely, a definition with many common elements was proposed by Fishbein and Ajzen (1975): "A learned predisposition to respond in a consistently favorable or unfavorable manner with respect to a given object." The evaluative or affective component (like/dislike or favorable/unfavorable) distinguishes attitudes from other concepts. Attitudes can be strong and well-formed or weak and broad, and are generally developed through various learning processes. Social scientists have developed and refined diverse methods for accurately measuring attitudes over the past 60 years. Many survey research efforts to explore interactions between people and the environment have focused on attitudes. For example, asking people how much they like or dislike the Bureau of Land Management is one way of measuring attitudes toward the agency.

Because attitudes are learned, they are subject to change. Substantial literature is devoted to understanding the nature of attitude change, whether by experience, new information, persuasion, cognitive dissonance, propaganda, behavior change, advertising, or other methods. An undeniable conclusion of this research is that attitudes, although defined as consistent evaluations of an object, are subject to manipulation.

[7] Trent (1995) summarized the results of numerous surveys that described people's attitudes, beliefs, and values relevant to understanding perceptions of natural resources and public land management in the Basin. Much of the material presented here is derived from that report.

Beliefs

Beliefs reflect what people think is true about something. Fishbein and Ajzen (1975) defined beliefs as statements indicating a person's subjective probability that an object has one or more attributes. Beliefs can be one reason for having a certain attitude. An example of a belief might be that the Forest Service accomplishes planned harvest levels, or protects habitat for endangered species.

Beliefs also are subject to change based on new information, life experiences, or other learning processes. Fishbein and Ajzen (1975) believed that attitudes and beliefs are part of a system that also includes behavioral intent, defined as "a person's intentions to perform various behaviors." Both beliefs and behavioral intentions have a strength component, which is based on people's perceptions regarding the likelihood that an object really does have some characteristic, or the subjective probability that a person will actually perform the behavior in question. Another component of beliefs is behavior, which is defined as observable actions.

Values

Values reflect things that people consider being precious. They are generally regarded as important life goals or standards of behavior toward which the person has a strong, positive attitude. "Values are the most important and central elements in a person's system of attitudes and beliefs" (Oskamp 1977). People's value systems could be viewed as building blocks of many attitudes and beliefs. Although dynamic like attitudes, values are more deep-rooted and resistant to change (Burch and Deluca 1984).

For some people, a core set of values can be so strong as to essentially dictate an individual's behavior in a wide range of settings and situations. Many of the toughest social issues facing our Nation today seem difficult or impossible to resolve because they are based on fundamentally conflicting and strongly held values. Value conflicts also form the basis of many disputes about natural resources, suggesting that such disputes are difficult to resolve in a manner acceptable to a wide range of stakeholders in public land management. Part of a land manager's job is to understand these various values and their influence on people's perceptions of land management actions.

Values, like attitudes and beliefs, change over time, creating new expectations and demands for public land management. Gale (1991), for example, argued that one reason for conflict over public lands in the West has been the increase in the variety of expectations about what goods and services such resources should produce. Ecosystem management is the BLM and FS's response to these changing social and cultural values and new scientific understanding of landscape ecology.

Guidelines for Using Attitude Surveys

Although basing public land management on prevailing public attitudes at any given point in time is dubious, the attitudes and the underlying beliefs and values of stakeholders should be considered. Measuring attitudes, however, is also a trying exercise because people's responses can be influenced by many factors, such as wording of questions; order, context, amount, and type of information provided to respondents; and social desirability. A major event can affect societal attitudes almost overnight. Sampling methods, survey administration, and analysis techniques all have specific effects on the validity and reliability of survey results and their general application to the population being surveyed.

A main information source for public attitudes toward natural resource issues was the Survey of Natural Resource Issues on Public Lands in the West (referred to as the CRB survey throughout this chapter), conducted in July and August of 1994 by scientists at Utah State University, Oregon State University, and Washington State University (Brunson and others 1994). The survey's intent was to provide the ICBEMP staff with specific information about attitudes of the local, regional, and national population toward important issues confronting the agencies managing Federal lands in the Basin. It was hoped that the survey would provide additional clarity in identifying the public's feelings about ecosystem management.

Four populations were sampled: eastside public (people living in Basin counties east of the Cascades); westside public (people in Basin counties west of the Cascades); national public (people from the 48 contiguous states); and project participants (people on the Eastside Ecosystem Management Project mailing list or who had participated in the scoping process). Response rates for the four sample groups were uniformly low, ranging from 18 percent of the national sample to 38 percent of the project participants. Because of the low response, the results were treated as responses of respondents only, not as representative of broader populations. However, the data were valuable in describing the range and types of attitudes, beliefs, and values that people hold.

Surveys were just one source of information on attitudes, beliefs, and values used in this assessment. Other sources, though not scientifically collected, provided insight into people's attitudes relative to issues important to the ICBEMP. Among the other information sources were issues identified during project scoping conducted by the EIS team, position statements submitted to the project by various groups and organizations, newspaper editorials and accounts of current events, journal articles, legal proceedings, and political cartoons.

Environmental Concern

A 1989 Gallup survey that explored public attitudes toward environmental protection and the environmental movement found that 76 percent of a national sample considered themselves to be either "strong" environmentalists or environmentalists. Nearly half reported validating this self-perception with behavior: 49 percent said they had contributed money to an environmental, conservation, or wildlife preservation group. In a more recent survey (Roper Starch 1994), 23 percent of a national sample described themselves as "active environmentalists," 56 percent said they were "sympathetic but not active," 16 percent claimed neutrality, and 2 percent were unsympathetic.

Dunlap and Scarce (1991) examined trends in attitudes toward environmental issues over the past 20 years, including issues such as threats posed by environmental problems, support for government actions, willingness to pay for environmental protection, perceived seriousness of environmental problems, and tradeoffs between environmental protection and economic development. When asked to name the two most important problems facing the United States, about 20 percent volunteered "the environment," a rate that has remained fairly constant. They concluded that, as of 1991:

> *Public concern for environmental quality has reached an all-time high. While questions about the strength of environmental concern remain unclear, growing majorities see environmental problems as serious, worsening, and increasingly threatening to human well-being.*

Dunlap and Van Liere (1978) called this set of attitudes the "new environmental paradigm" that supports maintaining the balance of nature and rejects the notion that nature exists solely for human use. In many polls, younger respondents who are part of the baby boom generation expressed values more sympathetic with this perspective than did older respondents. Yaffee (1994) believed this stronger set of environmental values would likely be maintained as baby boomers age.

The causes for increased environmental concern have been reviewed by several researchers (Dunlap 1992, Dunlap and Van Liere 1978, Hendee 1989, Kanagay and others 1994, and Steel and others 1994). Among the contributing causes identified were generational differences, technological advances, urbanized lifestyles that detach people from settings producing demanded goods, many well-publicized events worldwide that demonstrated the risks of substantial human impacts to the environment, and beliefs that the world may not be able to support ever-increasing numbers of people competing for finite natural resources.

The *Times-Mirror* Magazine's National Environmental Forum Survey (Roper Starch 1994) conducted in 1992, 1993, and 1994 was used to describe recent environmental trends. In 1994, a majority of respondents (53%) believed that environmental laws and regulations had not gone far enough, compared to 16 percent who felt they had gone too far and 23 percent who believed the right balance had been met. Younger Americans (age 18 to 34) were more likely to feel strongly that regulations do not go far enough (64%), compared to just 36 percent of those age 65 and older.

In 1992, 63 percent of the respondents believed that environmental laws and regulations had not gone far enough, compared to 10 percent who felt they had gone too far and 17 percent who said the right balance had been met. Although the relative ranking of these three response categories did not change from 1992 to 1994, a slight shift in attitudes was apparent; in 1994, more people believed that there was a balance or that regulations had gone too far.

Values Regarding Natural Resources

Natural resource values can be categorized in many ways. The following list is one effort to categorize the types of social values relating to natural resources that were provided by the social assessment chapter of *Forest Ecosystem Management: An Ecological, Economic, and Social Assessment* (FEMAT 1993). In that document, social values were categorized as:

- Commodity values: timber, range, minerals.
- Amenity values: lifestyle, scenery, wildlife.
- Environmental quality values: air and water quality.
- Ecological values: habitat conservation, biodiversity, threatened and endangered species.
- Public use values: gathering, subsistence, recreation, tourism.
- Spiritual values: sacred places.
- Health values: medicines.
- Security values: sense of social continuity and heritage.

The CRB survey contained a query about values similar to those in FEMAT. From a list of 17 factors concerning the future of public lands in the Basin, respondents were asked to rank the 3 most important factors to them and their families. The wide range of factors included ecological health, resources for future generations, several types of commodity production, outdoor recreation and amenities, salmon, and wildlife habitat.

The most important factor of all four population segments was resources for future generations. The national sample's next most important factors were wildlife habitat and ecological health; the westside residents' next priorities were outdoor recreation, wildlife habitat, and ecological health. Next important factors for eastside residents were quality place to live (just 2% behind the top concern), followed by outdoor recreation, and wildlife habitat; wilderness and wild and scenic rivers were rated as less important than hydropower and agriculture. Project participants rated ecological health second, followed closely by quality place to live; more of this group included timber production (25%), livestock grazing (12%), and economic opportunity (15%) as one of their top three. Eastside residents, who potentially would experience the greatest immediate impacts of ecosystem management, expressed priorities similar to the national population.

Steel and others (1994) explored a value dichotomy that they believed was central to explaining conflicts about Federal forest management: an anthropocentric or resource conservation focus that advocates wise use of forests for the betterment of humankind; and a more biocentric orientation that assumes the natural environment has inherent worth apart from any human use. Sociodemographic characteristics, self or group interests, sociopolitical orientations, and geographical location (residence) are some of the variables influencing whether people hold the "more traditional anthropocentric view of forests" or the "emerging biocentric view."

To test the role of residence in value orientation and to better understand related attitudes and beliefs, Steel and others (1994) conducted a survey of two populations: the national public and Oregon residents. To assess value orientations, they used an eight-item scale of statements about the relationship of people to natural resources. People indicated their levels of agreement or disagreement with each item; scores were then combined to yield a total score for classifying respondents as anthropocentric, biocentric, or intermediate.

The authors concluded that Oregonians, and especially the Nation's public, strongly supported a less commodity-based, more ecologically sensitive approach to Federal forest management. Both the Oregon and national samples tended to be more biocentric than anthropocentric, but the national sample was significantly more likely to have stronger biocentric views toward forests than was the Oregon sample. Younger respondents, women, members of environmental groups, and liberals were more likely to have biocentric orientations toward forests than were older respondents, men, people dependent on the timber industry, and self-described political conservatives.

The authors reported that Oregonians and national residents both responded in an anthropocentric manner to only one of the eight items: "Forest resources can be improved through human management." This apparent agreement, however,

could have resulted from different interpretations of the question; agreement with this statement does not necessarily indicate an anthropocentric viewpoint. One could assume that humans have altered some forest environments to the point they cannot recover if left unmanaged. If the goal is to restore forest health, for example, human intervention would be necessary to eliminate exotic species and allow the return of native species.

Steel and others also asked about attitudes toward nine Federal forest policy statements regarding wilderness, clearcutting, old-growth forests, tradeoffs between timber workers and old-growth preservation, and the role of economic vitality of rural communities in decisions. The results were not surprising. People with biocentric orientations were more likely to support bans on clearcutting, creation of wilderness, and protection of old-growth areas. Anthropocentric thinkers were more likely to support setting aside endangered species laws to preserve jobs, or making economic concerns a higher priority in forest decision-making. However, differences emerged between the Oregon and national samples. Anthropocentric thinkers who were Oregon residents were more likely than their national counterparts to support human uses of forests. For instance, 80 percent of the Oregon anthropocentric respondents agreed that endangered species laws should be set aside to preserve timber jobs, compared to just 31 percent of the national anthropocentric thinkers.

The CRB survey (Brunson and others, n.d.) included five items taken from the eight-item scale discussed above in the Oregon and national survey. In general, the responses of all four population segments (national public, westside residents, eastside residents, and project participants) indicated a preference for biocentric over anthropocentric viewpoints. Eastside residents tended to be slightly less likely to reflect biocentric value orientations.

The Economic Assessment (chapter 6) suggested that estimating economic benefits is easier for market resources than for nonmarket resources, meaning that utilitarian values are more easily measured than biocentric ones. However, literature on natural resource and recreation economics is replete with technique examples to estimate dollar values of nonmarket resources, such as non-use values associated with knowing a resource is there (Duffield and others 1994). Dollar estimates associated with non-use or passive use values of natural resource settings are 3 to 20 times greater than those associated with direct recreational use, a notion supported in the policy arena as well (Allen 1985). Duffield and others (1994) suggest that motives for holding non-use values, often referred to as preservation and existence values, include general environmental concern, altruism, and past recreational use of natural resources.

A national values poll commissioned by the Forest Service (Hammond 1994) was designed to discover major trends and themes based on people's responses to broad statements about public forest and grassland uses. The results were used by the Forest Service's Reinvention Team in considering agency changes. Several major themes emerged from the values poll. First, respondents wanted to maintain healthy public forests and grasslands. This was called the overriding theme, because people were more concerned about reaching this goal than about who did it or how it would be accomplished. The authors stated: "Apparently, most people in America are convinced that maintaining healthy public forests and grasslands is somehow tied to the quality of life in this country."

Second, respondents wanted to create recreational opportunities on public lands. Although the poll did not ask for specific activity or setting of preferences, people rated recreation highly. Curiously, Hammond supported this point in part based on respondents' agreement with the following statement which seems to make a different point altogether: "The Federal Government should balance the wilderness and recreational use of public lands with logging, mining, and grazing uses."

People believed that maintaining healthy public forests should be a primary Federal management objective and that human intervention was necessary to meet this goal. They believed that Federal

agencies, such as the Forest Service, best represent their interests in forest management (47%), compared to 21 percent who said they are best represented by special interest groups, 13 percent by state agencies, and 5 percent by the Congress.

Respondents also valued not compromising the long-term health of public forestland for short-term gains. Explaining this theme, the author stated: "The people in this country also seem to realize that the public forests must be preserved for future generations and that what is done today will impact tomorrow...Any short-sighted excesses of the past will not be permitted in the present and the public expects the Federal Government to be responsible for conserving forests for those yet to be born." A related theme, that the consumer needs of the American public should not be satisfied at the expense of the health of public forests, indicated to the author that the general public wanted to place consumer interests within the context of long-term health of public lands.

Finally, people believed that the Federal Government should assist state and local government agencies and private landowners in managing forestlands. This theme indicated two types of responses: (1) people want the Federal Government to discover and disseminate information needed to solve resource problems; and (2) people feel that "those who live in closest proximity should play the primary role in the way public forests are utilized and managed." These responses suggest a preference for Federal agencies to work in partnerships with local governments and communities to reach decisions, a finding consistent with other surveys of both local and national publics.

Sense of Place

One value not considered uniformly in past forest and rangeland plans is sense of place, which includes the meanings and images that regions, areas, or specific locations on the landscape have for people. Ecosystems are the intersection of natural forces, social and economic relations, and sociocultural meanings (Williams 1995). Ecosystem management recognizes the social construction of nature; space becomes place when people create and attach meaning to it (Williams 1995).

Place is how people relate to and express an experiential understanding of geographic areas. People's perceptions of "place" or the physical area with which they interact, whether for a few minutes or a lifetime, give that area special meaning to them, their community, and their culture. Humans associate and interact with geographic areas, whether physically, spiritually, or through various media, and form long-term bonds of attachment with these places. Research shows that place attachment is customarily passed down through generations, becoming part of people's heritage. Place is an integral component of community life because collective definitions of socially important places help to form and maintain community bonds and priorities.

Galliano and Loeffler (1995) stated: "Perhaps one of the most significant characteristics of ecosystem management is its ability to substantiate the emotional and symbolic meanings of natural resources on our country's public lands." The values and meanings of the Basin's places serve as significant factors reflecting the human dimensions of ecosystems and serve as links between social experiences and geographic areas. Recognizing this important element, the *Framework for Ecosystem Management in the Interior Columbia Basin* (Haynes and others 1996) provides a strong alliance between ecosystem management and the social realities of place by having one of its five primary objectives be to "manage for the human sense of place."

The notion that people define landscapes based on their meaning, utility, and image is not new. Through their traditional subsistence economy, Indian peoples gained a very detailed knowledge of the land, including locations of each resource needed to sustain their lives and culture. Attachment to ancestral lands is reflected by the return to favored areas and campsites during annual subsistence rounds. Place importance is also reflected by language such as place names, which relay knowledge of the land by referring to a specific place's plants and animals, the actions of its people, its spiritual role, or other important site characteristics.

Understanding the concept of place in ecosystem management allows managers to more actively inventory and understand the meanings that people attach to the lands and resources within the manager's administrative jurisdiction. The notion of measuring and incorporating human sense of place into public land management is relatively new and has yet to be adopted uniformly by any land management agency. However, there is ample literature pointing to the importance of place that suggests ways to measure and manage for it (Andrews 1979, Brunson 1993).

Williams (1995) defined four different types of meaning attached to landscapes:

- Scenic/Aesthetic—Use of formal models from landscape architecture and environmental psychology to map physical characteristics, landscape themes, visual character, and scenic integrity of various landscapes. The current scenery management systems of the BLM and FS incorporate methods to measure and map these types of place meanings.
- Activity/Goals—Traditional utilitarian philosophy of natural resource management, which assigns meanings to geographic units by assessing their capacity to promote behavioral and economic goals. One example is the Recreation Opportunity Spectrum, which identifies recreational activity-oriented meanings. Such meanings, however, include other factors such as meanings associated with production of commodities. Typically, resource management agencies have developed extensive methods of identifying, mapping, and managing these types of place meanings.
- Cultural/Symbolic—Human emotional, spiritual, and symbolic identification with place, often referred to as the sense of place where natural resources are valued not only for functional purposes, but also places to which people, as a community, are attracted and become attached.
- Individual/Expressive—Potential for people to assign highly individualized meanings to places as a mechanism by which they construct and affirm a "sense of self."

Just as ecosystems must be viewed as hierarchies, so must places. The four approaches listed above can be viewed as different methods for assessing place meanings, ranging from the very broad and tangible (scenic/aesthetic) to the more familiar, often personal and intangible (individual/expressive). A BLM or FS unit manager may consider all four meanings when preparing a watershed or site analysis where the geographic area is relatively small and the desired level of specificity is high. At larger scales, such as the Basin ecoregion, where place inventories are comparably extensive, it would be unreasonable to attempt identification of individual/expressive place meanings. Because neither cultural/symbolic nor individual/expressive meanings can be easily mapped using geographic rule-based systems, these two meanings can only be identified through interactive processes such as those used by Galliano and Loeffler (1995).

Place assessment is a way to inventory the locations, names, and broad attachments that many peoples share for geographic areas within the Basin. Surveys of resource users and communities have demonstrated that the strength of place attachment can be quantified for multiple places and at multiple geographic scales (Williams 1995). Scenic/aesthetic and cultural/symbolic meanings of place were successfully mapped and defined at both a mid-scale (in the Yakima and Silvies basins) and at a Basin-wide scale (Galliano and Loeffler 1995). The issue of scale in defining places having special meaning is important (Tuan 1974). Although Galliano and Loeffler (1995) were successful at using ecological subsections as proxies in their effort to map place meanings in terms of scenic/aesthetic elements across the entire Basin, they recommended mapping places at a finer, more meaningful scale such as the community scale. The finer scale, which provides a positive basis for people and managers to understand the multiple meanings and values that can be attached to landscapes, is a sound basis and methodology for mutual learning and collaboration. Sense of place is particularly meaningful at the community scale; residents' common definitions of local places are the characteristics contributing to community cohesiveness and definition.

Attitudes and Beliefs Relevant to Ecosystem Management

Because understanding people's perceptions of ecosystem conditions helps to explain their attitudes toward ecosystem management, the following text describes both beliefs and attitudes. Many people believe there are problems with ecosystem health in the Basin. The CRB survey contained a question that first informed respondents: "Recently there has been a lot of talk about whether public lands in the western U.S. are deteriorating due to current management practices." Respondents were asked to indicate on a seven-point scale whether they believed that no serious environmental problems existed, or that serious environmental problems already existed in the western United States. The clear majority of respondents (between 70 and 78%) in all four samples fell on the "serious problems exist" side of the scale, with project participants expressing the strongest attitudes. Although the rather severely worded introduction may have influenced respondents, the results nonetheless suggest that the public supports reexamination of Federal land management practices.

Regarding beliefs about forest health, Frederick and Schneiders (1994) found that 58 percent of a national sample rated the Nation's forests as healthy, although just 13 percent of these rated forests as "very healthy" and 45 percent believed forests were "somewhat healthy." Of the 27 percent who believed U.S. forests were unhealthy, only 5 percent said they were "very unhealthy." Across every region, people tended to rate forest health conditions in their own part of the country as better than the Nation as a whole. For example, in the Pacific Northwest, 72 percent rated forests as healthy or very healthy, and 25 percent believed forests to be somewhat healthy or very unhealthy.

Comparable results were found in a poll of Idaho voters conducted for the Idaho Forest Products Commission (Moore Information, Inc. 1994); 58 percent rated forests in the state as healthy, and 32 percent believed they were unhealthy. Southwest Idaho residents, however, were either evenly divided in their beliefs or thought that the state's forests were not healthy. Men age 45 and older were less likely to believe forests were healthy (47%) than were younger men (60%) or women of all ages (62%).

Brunson and Steel (1994) found that "little research has examined public knowledge or beliefs about rangelands." Their study, one of the exceptions, found that "the public believes rangelands are overgrazed, seriously eroding, losing riparian vegetation, and that conditions are getting worse instead of better." Not surprisingly, this sample favored managing rangelands for broad ecosystem functioning rather than livestock production. They favored increasing fees to "fair market value" for grazing on public land, but wanted fees phased in to allow ranchers time to adjust. This desire reflects the broader trend of public concern to focus on restoring ecosystems, but in ways that consider and mitigate related socioeconomic impacts.

Although Brunson and Steel believed that the results "reflect a broad national trend toward increasing environmentalism." Respondents felt that a high priority should be given to the needs of affected local communities when making decisions about Federal rangeland management. The respondents distinguished communities from affected local industries, whose needs were perceived to have much lower priority. The authors noted that the results, in general, paralleled those of an earlier study on forest management, except for the increased proportion of respondents who were unsure about their feelings. This is consistent with other surveys, likely because range management issues and the BLM are less known to the general public than are forest management issues and the Forest Service.

Active and Passive Management Approaches

Brunson (1993) stated that ecosystem management would be most acceptable to people who believed it to be a more natural management approach. The challenge, he believed, would be to convince people that active human manipulation is more acceptable than letting nature take its

course. This issue was reflected in one Basin EIS issue statement about whether ecosystem and forest health restoration is possible and, if so, is it better to actively manipulate ecosystems and mimic natural disturbance regimes, or is it preferable to "let nature heal itself."

A national survey on forest management (Frederick and Schneiders 1994) found that 52 percent favored human management of forest areas, while 40 percent said nature should be allowed to take its course. This preference for human management was even stronger among Pacific Northwest residents (59% and 28%, respectively).

Ecosystem Disturbances

A major emphasis in ecosystem management has been to mimic natural processes, or at least to design activities based on knowledge of natural disturbance patterns. It is important to understand how attitudes toward such natural processes relate to attitudes toward management. Brunson (1993) hypothesized such attitudes may be one possible reason for people not to accept ecosystem management: "...natural processes being simulated (disturbance regimes) carry a negative label." This hypothesis has been supported in studies of people's attitudes toward many disturbances, including fire, diseases, and insects, as well as by public reactions to isolated Federal or state agency actions.

Much of the available research on people's attitudes toward specific ecosystem processes and management actions is summarized below to provide decision-makers with a better understanding of the public's attitudes, as well as factors influencing their attitudes, specific to fire, timber harvest, insect and disease infestation, and roads.

Fire—One national survey (Frederick and Schneiders 1994) found that 55 percent of respondents thought the Forest Service should attempt to extinguish all fires to preserve as much of the forests as possible, while 36 percent said more fires should be allowed to burn their course because fires are a part of the forest's life cycle. Pacific Northwest residents had similar opinions, but by a closer margin (46% and 39%, respectively).

The same survey found support for using controlled fire; 49 percent favored use of controlled fire by Federal agencies to thin forests so wildfires are less damaging, compared to 42 percent who opposed controlled fire use due to concern about potential for fire spread and air pollution from the resulting smoke. Support was stronger in the Pacific Northwest, with 54 percent favoring use of controlled fire compared to 38 percent opposed. Women were more likely to favor extinguishing all fires and were less supportive of controlled burns than were men.

The CRB survey informed respondents that "some people favor the introduction of fire in Federal forest lands to control disease, insects, and excessive fuel levels. Others suggest this use of fire is unnecessary and dangerous." This question was one of the few that the four samples agreed with completely. The top choice of all four samples, by a wide margin, was: "We should suppress wildfires in Federal forests managed for timber; however, controlled fire may be used to protect forest health." The second choice of all four groups was: "We should suppress wildfires in Federal forests only if they threaten human lives or property; otherwise, we should allow fire to resume its natural role in forests."

The third-ranked statement was: "We should suppress fire in all Federal forests managed for timber, and use pesticides or salvage logging if forest health is endangered." Although this statement was rated as significantly less attractive than the second choice for most samples, eastside residents ranked it only slightly lower. It may have been less attractive due to its reference to pesticides, based on other responses showing that chemical pesticides were opposed strongly by all groups. This statement's appeal to eastside residents may be related to its reference to salvage logging. Far behind the other options was: "We should suppress fire in all Federal forests." This was favored by less than 10 percent in each sample. Between 10 and 18 percent had no opinion.

Interpretation of these responses is hindered by the noncomparability of the various statements. For example, one statement included three separate elements, including one element that was not mentioned in any other statement. This noncomparability creates difficulty in determining to which aspect of the question people were keying their response. Nonetheless, the groups' rare agreement suggests that support for use of controlled fire to protect forest health may be acceptable to diverse publics.

Beliefs about the causes of wildfires can influence people's attitudes toward fire management. Moore Information, Inc. (1994) asked Idaho voters which of five factors they believed contributed most to the severity of forest fires in Idaho the previous summer. Fifty percent attributed fires to the drought, 19 percent to acts of nature, 12 percent to lack of forest management, 11 percent to over-dense timber stands, and 1 percent to insects and disease.

In a review of public perceptions of air quality in the Basin, Miller and Deller (1994) found that the public believed that wood stoves, traffic, dust from unpaved streets, and agricultural burning all contributed to air pollution. The specific location and purpose of the various surveys determined the nature and range of responses. The authors did not identify studies about perceptions of smoke from natural or prescribed fires, but did mention that providing the public with specific information about the reasons, location, timing, and effects of a prescribed burn results in a higher level of acceptance.

Timber harvest—Perhaps the most controversial of all forest management actions is timber harvesting on public lands. Moore Information, Inc. (1994) found that 76 percent of the Idaho voters who were surveyed were supportive of "thinning and other forest management techniques as a way to improve forest health and reduce the potential for catastrophic wildfires." Although the authors concluded that survey results indicate "widespread support for thinning among all voter subgroups," the question assumes that thinning always improves forest health and reduces fire risk. More important, use of the term "catastrophic" is likely to provoke support regardless of how people actually feel about the issue; nearly everyone is opposed to a catastrophe. We can still assume, however, that many Idaho voters support thinning practices. Thinning was also found acceptable in a survey of Blue Mountain area residents (Shindler and Reed 1996).

A related question asked people which of the following two positions did they agree with most:

- Thin forests to improve conditions for remaining trees and also for wildlife, provide jobs, reduce wildfires, and make forest conditions more similar to presettlement conditions.
- Allow nature to take its course in the forests by not harvesting timber under the assumption that logging can harm the scenic and recreational value of the forest area, the fisheries, and wildlife.

The first statement was the choice of 71 percent, and the second was chosen by 17 percent. Based on this ratio, the authors concluded that Idaho voters support thinning forests to improve forest conditions over allowing nature to take its course. They pointed out, however, that a nationwide survey posing the identical question found considerably less support for thinning (51%), compared to allowing nature to take its course (43%). Follow-up discussion with respondents would be valuable to determine which of the many attitudes and beliefs inherent in these complex statements led respondents to select one over the other.

In their nationwide survey, Frederick and Schneiders (1994) found divided views regarding salvage logging: 48 percent agreed that logging in burned-over areas should proceed rapidly to reduce the risk of further fire and that legal challenges should be limited so the trees do not decay and lose their value; 43 percent agreed with the statement that logging in burned-over areas should proceed only after comprehensive environmental review, public input, and resolution of legal challenges, even if the value of the timber is at risk.

A related question informed people that after forest fires, a considerable number of dead trees remain in the burned-over areas, and asked people to choose between two statements:

- Log some dead trees and use the timber sale revenue to help pay the cost of fighting wildfires and to restore the forest and wildlife habitats.
- Leave all trees in the forest to decay to provide nutrients and support for forest wildlife and the new plants that reestablish the forest following the fire, and lose revenue that logging would have brought.

The first statement was favored by 51 percent, and the second by 43 percent; support for salvage logging was stronger in the Pacific Northwest. The relatively narrow margin of support nationally suggests that people are persuaded by both arguments. One key term may be "some dead trees," which connotes very limited entry and impacts, compared to logging "most or all dead trees" to which people may have responded differently.

The CRB survey contained several questions related to logging practices that could be used to meet ecosystem goals, including selective logging, clearcutting in burned or insect-infested areas, selective cutting in burned or insect-infested areas, and selective harvesting to prevent forest diseases and infestations. Of the people who had an opinion, the greatest support among all four samples was for selective harvest methods to prevent forest diseases and infestations; the only opposition, which was slight (14%), was from project participants. All four samples also supported selective logging practices in general and were just slightly less supportive of selective cutting in burned or insect-infested areas, which was opposed by about 15 percent of the respondents in each sample. The greatest diversity of opinion was about clearcutting in burned or insect-infested areas; respondents in all samples were nearly equally divided, although eastside residents showed the strongest support.

Insects and disease—The CRB survey asked whether people agreed or disagreed that "insect outbreaks on public lands should be allowed to run their natural course." All four samples disagreed, at rates ranging from a high of 64 percent (eastside residents), to a low of 51 percent (westside residents). Except for the project participant group, more people were neutral than in agreement with the statement. This was especially true for the national group, 31 percent of whom were neutral, possibly due to their not understanding or having strong beliefs regarding the issue and its implications. The project participant group held the most extreme viewpoints, with just 12 percent being neutral. The widespread disagreement with the statement seems reasonable whether or not respondents understood the role of insects in forest ecosystems. When questions include the phrase "insect outbreaks," which has a negative connotation, disapproval is fairly assured in the absence of compelling information to the contrary.

Roads—Frederick and Schneiders (1994) asked national respondents to choose between two statements regarding managing forest areas where roads have not been built. Fifty-five percent did not favor building roads, stating roads create soil erosion and destroy the forest's wild nature; 40 percent favored building more roads to increase access for fighting fires, allow the forest to be thinned, and support recreational uses. Pacific Northwest residents slightly favored building more roads (48% to 46%). Women were more strongly opposed to constructing new roads than were men; Democrats and Independents were much more opposed to new road construction than were Republicans, who were evenly divided on the issue.

Another CRB survey question about roads asked people whether they supported road closures in ecologically sensitive areas where recreation occurs. Although all four samples supported this position as a strategy to improve conditions on public lands, about 26 percent from each of the eastside and participant samples opposed it.

Attitudes Toward Endangered Species

The Endangered Species Act has a history of broad public support. In a recent nationwide poll (Roper Starch 1994), 51 percent of the American public felt that regulations protecting endangered species of plants, animals, and insects have not been sufficient; 16 percent believed the regulations have gone too far; and 26 percent said the balance was right. The question was one of five elements of environmental concern; the others addressed air pollution, protection of wild or natural areas, protection of wetland areas, and water pollution. More people said that endangered species laws have gone too far compared to laws in the other four areas. Similarly, protecting endangered species was the least likely of the five areas to be viewed as not going far enough. In 1992, a higher proportion (31%) said there was a balance, fewer (11%) said laws and regulations had gone too far, and the same proportion (51%) said laws had not gone far enough.

A related question described the Endangered Species Act as requiring "the Federal Government to take whatever steps are necessary to prevent any type of plant, animal, or insect species from becoming extinct, even at a cost to landowners, businesses, or the local economies where species live." The question posed was: "Do you agree all endangered species of plants, animals, and insects should be saved regardless of the costs, or do you think the policy should take cost into consideration?" Nearly two-thirds (63%) said costs should be considered (compared to 50% in 1992); 29 percent agreed all species should be saved (compared to 38% in 1992), and 5 percent said it depends on the species.

In 1992, respondents were asked what they believed to be good arguments for saving species; 79 percent said the loss of life-saving medicines was a strong argument, 76 percent said that extinctions can upset the delicate balance of nature, and 63 percent said species have rights to exist and it is people's moral duty to help them. This reasoning describes some underlying values that lead people to support endangered species legislation.

A 1991 survey of Oregon residents (Market Decisions 1991 In: Duda and Young 1994) found that 66 percent of residents believed the Oregon Department of Fish and Wildlife "should operate a program to prevent fish or wildlife from declining to the point of becoming extinct, and protect and promote recovery of species that are already threatened or in danger of extinction."

The CRB survey also contained questions on endangered species management. One question asked respondents about their level of agreement with the statement "Greater efforts should be made to protect rare plant communities on public lands." In all four samples, more people agreed than disagreed. Agreement was strongest (65%) within the national sample and weakest (42%) for eastside residents. As with many other questions, the project participant group was the most polarized about providing more protection for rare plants on public lands; this group had the lowest level of respondents (13%) saying they were neutral, 49 percent agreeing, and 38 percent disagreeing.

Another CRB survey question was more explicit about potential tradeoffs: "Endangered species laws should be altered to maintain timber and ranching jobs on public lands." A majority (52%) of national respondents disagreed; just 29 percent agreed. Westside residents followed the same trend, but were more divided in their attitudes; 45 percent agreed and 39 percent disagreed. A majority of eastside residents (53%) agreed with the statement, while 30 percent disagreed. Again, ICBEMP participants were the most polarized; just 5 percent were neutral, 48 percent disagreed, and 47 percent agreed with the statement.

Overall, the results suggest that although remaining strong, support for endangered species laws and regulations may have decreased slightly over the past three years. This decrease may reflect that the public is increasingly concerned with seeking a balance between species protection and costs to society. This concern is especially strong among eastside residents.

One set of questions in the CRB survey was directed specifically toward salmon, many species of which are either listed or under consideration for listing. The four groups considered themselves to have very different levels of knowledge; 73 percent of the project participants, 43 percent of westside residents, 40 percent of the eastside residents, and just 13 percent of national residents said they were well informed about the status of salmon runs in the Pacific Northwest.

When presented with the general statement that greater protection should be given to fish, such as salmon, on public lands, all four samples agreed; the strongest level of agreement came from westside residents (72%) and national respondents (68%), compared to 55 percent of the project participants and 54 percent of the eastside residents. The project participant sample contained the largest proportion of people who disagreed (32%).

Respondents were presented with a list of 11 factors potentially contributing to the decline of salmon runs, and asked how much of a threat they believed each factor to be. National respondents were the most likely group to say they did not know. Three factors were perceived as the greatest threats by people both inside and outside the Basin: commercial ocean fishing by foreigners; water pollution; and dams. Habitat destruction on public and private lands was rated as a threat, but of less severity, and as a slightly higher threat on forestlands than on rangelands. Although patterns of response were fairly consistent across the four samples, project participants were far more likely to cite dams as a definite threat.

Moore Information, Inc. (1994) found that Oregon residents listed hydroelectric dams as the factor most responsible for declining salmon populations (39%), compared to too much fishing (19%), industrial and commercial development (18%), timber harvest activities (7%), and marine predators (7%). Idaho residents listed dams as the biggest factor in declines in Idaho's salmon populations (69%), followed by mining (40%), sport and Indian river fishing (39%), logging (35%), irrigation (31%), ocean fishing (29%), and grazing (19%). Just over half of the respondents (53%) agreed and 31 percent disagreed that there is adequate spawning habitat in Idaho rivers and streams to support increased populations of salmon and steelhead.

A follow-up question on the CRB survey asked about tradeoffs between recovery of salmon and issues such as employment, recreation, irrigation, and hydropower. The response format was a seven-point scale, with one end labeled: "Highest priority should be given to salmon, even if there are negative socioeconomic consequences," the other end labeled: "Highest priority should be given to socioeconomic considerations, even if there are negative consequences for salmon," and the midpoint labeled: "Salmon recovery and socioeconomic factors should be given equal priority."

About 40 percent of the eastside, westside, and national samples chose the midpoint response. Of the remainder, national and westside residents preferred giving priority to salmon by nearly a 3:1 margin, while eastside residents were equally divided on both sides. Project participants were again more polarized, with only 18 percent choosing the balanced viewpoint; 48 percent thought salmon should be given priority and 36 percent thought priority should be socioeconomics.

Attitudes Toward Tradeoffs in Public Land Management

As demonstrated above, one method of determining people's attitudes about natural resource issues has been to pose situations that represent tradeoffs between important values. However, one problem with many survey questions about tradeoffs is that they tend to set up dichotomies by asking people which is better, instead of exploring avenues of compromise or consensus. This approach casts the research and the policy issues being studied in a win or lose context, which may not represent actual true choices and can reinforce myths and stereotypes. In fact, most such debates do not really pit socioeconomic considerations against biological ones; they focus on conflicts about human values and priorities.

Despite this, one of the more common findings is that, when given the option, people will be optimistic that balanced solutions can be found. For example, a recent national poll (Roper Starch 1994) found that 90 percent of respondents agreed that: "We can find a balance that will allow economic progress and protection of the environment." However, more people agreed strongly with this statement in 1992 (58%) than in 1994 (49%). A related question asked people whether environmental protection and economic development could coexist or whether choices must be made; 66 percent believed the two could fit together, and 25 percent believed a choice was imperative. The response differences to these two questions are difficult to reconcile, pointing to the importance of subtle wording, such as asking people to choose between two options instead of asking for level of agreement with a single statement.

A follow-up question made the tradeoff more explicit, asking whether people believed economic development or environmental protection was more important when finding a reasonable compromise was impossible. Sixty percent thought environmental protection was more important, compared to 22 percent who gave more importance to economic development. When summarizing such results, it is important to distinguish very general questions such as this one from more specific questions that provide information on the type, location, purpose, costs, and methods of protection and development.

The Roper Starch survey also asked people whether they believed the only way to preserve wildlife, natural areas, and natural resources was to prevent development and restrict most other human activity in these areas, or whether these goals could be accomplished while being used to benefit the economy and the public. The first statement was chosen by 22 percent, and the second by 72 percent. This ratio may reflect another indicator that many people believe a balance can be found, or the ambiguous phrase "restrict most other human activity" could have been rejected as over-protection by many respondents.

The CRB survey contained several questions about tradeoffs, especially relative to salmon and endangered species. When asked about their agreement with the statement: "Survival of timber workers and their families is more important than preservation of old growth forests," national respondents expressed the highest levels of disagreement (54%) and eastside residents the lowest (36%). Eastside residents were the only sample that had a higher proportion of respondents agree with the statement than disagree. Somewhat surprisingly, the eastside residents had the highest proportion of people professing neutrality (25%). The sample of project participants again demonstrated their polarization; this group had the most people who strongly disagreed (30%), as well as the most who strongly agreed (22%).

Attitudes Toward the Federal Government

The continuing debate about the appropriate role of the Federal Government in shaping our society is a prominent political issue. For example, people who favor minimal government intervention in many arenas may oppose the active nature of ecosystem management, as well as the Federal Government's involvement.

Concern about the role of the Federal Government is reflected by county rights movements, which claim that Federal administration of public land is illegal. Starting with Catron County, New Mexico, in 1991, about 70 counties have enacted or are considering similar measures to change administration of public lands. In recent years, there has also been increasing social discussion about returning Federal lands to the states, or to American Indian tribes. However, an alternative reflection of county concerns and attitudes toward the Federal Government was the establishment and direction of the Eastside Ecosystem Coalition of Counties, a group created to provide input to the ICBEMP. The Coalition seeks to represent community interests, rather than individual viewpoints, and to provide a forum for discussing the public's opinion on community values. It is

specifically stated that the Coalition is not an advocate for special interests, nor a forum that trades one use for another, nor a forum for advocating elimination of the role of the Forest Service, Bureau of Land Management, or other federal agencies.

People's trust in the Federal Government is a major issue, because trust is an important type of belief influencing people's attitudes and behaviors about ecosystem management. It is therefore important to measure people's trust in the agencies and other institutions having roles in ecosystem management, such as other federal agencies, scientists, local governments and communities, national and regional publics, and the Congress. Attitude toward these institutions is another reflection of the ease or difficulty expected in obtaining public acceptance of ecosystem management.

Brunson (1993) pointed out that some people may be skeptical of ecosystem management, believing it to be a guise for finding "a level of timber harvest that reduces dissent to tolerable levels while adhering as closely as possible to the status quo." He concluded that public acceptance or preference for ecosystem management will be based partly on people's beliefs about its probability to actually produce desired conditions. Because ecosystem management is a new concept, people may not yet have formed beliefs about its effectiveness. Their beliefs may therefore depend more on past experiences with public agency attempts to mimic or work with natural events, which have had mixed success.

To many people already skeptical about the motives of the Federal Government, ecosystem management connotes attempts by the Federal Government to regulate private land uses. One reason for this concern is that, because ecosystems do not begin or end at public land boundaries, the assessment addresses resources on all lands within the Basin, not just Federal lands. Although the ICBEMP charter and other descriptive materials emphasize that the intent is only to apply ecosystem management to public lands managed by the FS and BLM, the act of inventorying resources on non-Federal lands makes many people suspicious that the next step may be increased regulation of those resources.

Level of Trust in Various Institutions

A fundamental issue affecting how the public perceives ecosystem management is the public's level of trust that agencies have the knowledge, willingness, and ability to implement required programs and activities. Many public participants in the ICBEMP have expressed skepticism about agencies' abilities. However, in one national survey (Frederick and Schneiders 1994), 74 percent of respondents gave the Forest Service favorable ratings compared to 8 percent unfavorable; favorable ratings were strong in every region across the Nation. The BLM was perceived less positively, with favorable ratings from 33 percent and unfavorable from 25 percent. The two agencies were rated by different numbers of people, because 43 percent of the national public either had not heard of the BLM or didn't know enough about the agency to state an attitude, compared to just 19 percent for the Forest Service. In the Pacific Northwest, where more people are familiar with the BLM, ratings remained about the same (42% favorable and 36% unfavorable).

Although the national sample had positive attitudes toward environmental organizations (64% favorable compared to 21% unfavorable), ratings by Pacific Northwest residents were lower (49% favorable and 46% unfavorable). Timber companies were viewed positively (36% favorable and 21% unfavorable), especially in the Pacific Northwest (57% favorable and 24% unfavorable). The same survey also asked about state forest agencies; although many respondents did not express an attitude, nationwide 47 percent (and 60% in the Pacific Northwest) gave favorable ratings compared to just 6 percent unfavorable.

Another national survey (Roper Starch 1994) found that 15 percent said they had a highly favorable opinion of most environmental groups, an additional 59 percent had moderately favorable opinions, and 23 percent had unfavorable opinions. Fifty-five percent had never contributed money to any environmental group, and 41 percent said they were unlikely to do so in the near future.

Moore Information, Inc. (1994) asked Idaho voters which of the following two groups did they agree with more about logging and the environment: forest products companies "who say that modern logging practices are an ecologically sound component of forest management plans," or environmental groups who say "logging is generally destructive to Idaho's forest environment." Fifty-six percent said forest products companies, 20 percent said environmental groups, 12 percent said both, and 7 percent said neither. However, the introduction to the question and characterization of each group's position really questions whether Idaho voters are supporting the statements or the respective groups.

When asked about the relative roles of the Congress and the Forest Service, 74 percent believed that the Congress should give agencies such as the Forest Service more flexibility to manage Federal forests in response to changing conditions; only 17 percent said the Congress should closely regulate such agencies because they cannot be trusted to manage forests wisely.

Finally, the survey asked about trust in scientists. Nationwide, university scientists were the most respected (by 43% of respondents), compared to environmental group scientists (21%), Federal forest agency scientists (16%), and timber company scientists (7%). However, in the Pacific Northwest, timber company scientists were twice as likely to be judged as credible than were scientists working for environmental groups. The authors concluded that trust in Federal agencies was strong and that the public takes a balanced approach to forest management issues: "The survey's findings provide encouragement for those who would attempt to educate the public and raise awareness of these issues, in order to promote better-informed public participation in the decisions which must be made in guiding forest management policy" (Frederick and Schneiders 1994).

The CRB survey obtained different results in querying about people's level of trust in institutions. Trust levels in government agencies were generally low in the Basin. For example, 42 percent of the eastside residents, 37 percent of the westside residents, and 31 percent of the project participants had moderate-to-great levels of trust in the Forest Service. Comparable figures for the BLM were lower: 31 percent, 26 percent, and 27 percent, respectively. The U.S. Fish and Wildlife Service received high ratings of trust from the eastside (47%) and westside (46%) residents, but was rated low by project participants (29%). Another survey (Roper Starch 1994) of Idaho, Oregon, and Washington residents showed very low levels of trust in government as well, but did not query about specific agencies. In the Roper Starch survey, the Federal Government as a source of information about the environment was rated fifth, after environmental groups, industry, the media, and university scientists.

In the CRB survey, other entities such as the Army Corps of Engineers, Bonneville Power Administration, and Native American governments uniformly received even lower ratings, moderately or greatly trusted by just 11 to 28 percent of respondents. Urban communities in the Basin, national public opinion, and federal courts also were less trusted, with most ratings in the 20 percent range. However, the distinction of least-trusted of all institutions was the Congress, in which just 8 percent of the eastside residents, 7 percent of the westside residents, and 6 percent of the project participants had moderate-to-great levels of trust.

The authors concluded that the general public places its greatest trust in local residents, the western United States public, the U.S. Fish and Wildlife Service, Forest Service, and university scientists. Rural community residents and university scientists were the only entities trusted more than distrusted by project participants. The project participants generally had higher levels of distrust than did other samples, which could be viewed as discouraging by the agencies, who would hope that increased familiarity would increase trust. However, project participants tended to have the most polarized views of any of the samples, suggesting that they began the process with strong viewpoints and, perhaps, were motivated by their lower levels of trust in the agencies.

A study of Idaho residents provided additional evidence for a relative lack of trust in the Federal Government, with 33 percent of respondents claiming the greatest confidence in local governments, 33 percent in state governments, and 20 percent saying they had no confidence in any level of government (Boise State University 1992). About 50 percent of respondents said that local government was the level most responsive to their needs.

Brick and others (1995) conducted a survey of residents in five counties surrounding Hells Canyon National Recreation Area (three northeastern Oregon counties: Wallowa, Baker, and Union; and two Idaho counties: Nez Perce and Idaho). They found that respondents reported having "some" to "a lot" of trust in community residents, local landowners, and locally owned businesses to manage the region's natural resources. This compared to "a little" to "some" trust in county commissioners, the FS, BLM, scientists, and state fish and wildlife departments, and to "no" or "little" trust in trade unions, non-profit environmental organizations, and out-of-state corporations.

People's beliefs about the trustworthiness of various institutions should correlate with their beliefs about assumed roles for institutions in influencing decisions about public land management, which would mean the greater the trust, the greater the influence. This hypothesis is only partially supported by available data. For example, the CRB survey found that eastside and westside residents, as well as project participants, believed that rural communities in the Basin, the western United States, public opinion, and university research scientists—all of whom they trusted—should have a moderate-to-great deal of influence in public land management.

The FS and BLM received much higher ratings on the measure about influence than on trust, with 46 to 56 percent of respondents from each population segment saying the two agencies should have a moderate-to-great deal of influence. The biggest difference, however, was the U.S. Fish and Wildlife Service (USFWS): 56 percent of eastside residents, 62 percent of westside residents, and 82 percent of project participants said USFWS should have a moderate-to-great deal of influence. These ratings may reflect people's acknowledgments of the agencies' legal responsibilities and authorities.

Respondents generally agreed that the Congress and Federal courts should have much less influence than Federal agencies or more-trusted institutions. This stance should be viewed as a positive finding and also as people's preference that the public and managing agencies work together to resolve issues, rather than relying on Congress to legislate solutions or the courts to make the ultimate decision. In other words, this could reflect a willingness to work in a collaborative fashion.

Steel and Brunson (1993) asked a national and an Oregon sample to whom government officials should be most responsive when making decisions about Federal rangelands. Both samples believed that government should be most responsive to affected local communities. National respondents believed that governments should then give the most attention to the following, and in the priority listed: national public opinion, government natural resource agencies, environmental groups, local affected industries, states' public opinions, and global and international opinion.

Oregon respondents believed governments should then give the most attention to the following: states' public opinion, local affected industries, national public opinion, government natural resource agencies, and environmental groups. Comparable results were reported in a national and Oregon survey regarding Federal forests (Shindler and others 1993). Respondents in the survey of five Hells Canyon area counties (Brick and others 1995) strongly agreed that "national forests belong to all Americans, but local people living near the forests should have the most say in management of the forests."

These findings appear to indicate that people favor downplaying the role of special interest groups. Perhaps this reflects agreement with a viewpoint expressed by Yaffee (1994) that while interest groups are important elements of our collective choice processes, their dominance is problematic in several ways: "Since they are primarily single-interest oriented, they promote the fragmentation of values and public purposes...that help agencies and decision makers craft effective policy direction."

These results show some of the similarities and differences between regional and national publics. Most interesting is the agreement that local communities should have a strong voice in decisions about Federal forests and rangelands. These results demonstrate the public's clear interest in having a greater role in natural resource decision-making. This involvement role is consistent with the public participation philosophy of ecosystem management, which requires close and frequent collaboration with the public and stakeholders in public land management (see following discussion on role of the public for more detail).

Attitudes Within the Forest Service

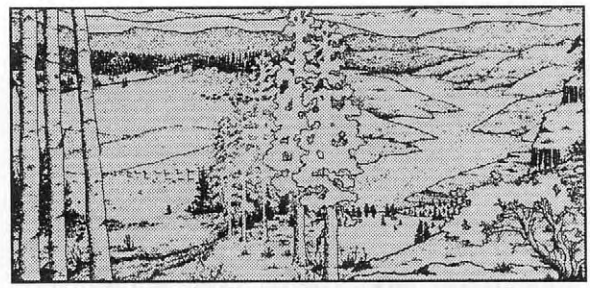
Several recent surveys of Forest Service employees provide a portrait of agency culture and the attitudes, beliefs, and values of agency employees (comparable studies of BLM employees were not found). A 1991 study examined value orientations of 1,900 Forest Service employees (Cramer and others 1994). A central finding was that "employees of the USFS tend to believe that the traditional priorities on timber and grazing are greater than their own values and the values of the American public. Furthermore, they believe that a greater priority ought to be given to recreation, wildlife, and water management rather than the traditional priority of timber." Employees believed that agency priorities were slowly aligning with the ecosystem values held by themselves and the public.

A 1992 survey of Forest Service line officers and staff (Mohai and others 1994) asked respondents to list the most important positive changes the agency had made over the last 10 years. Line officers and staff alike gave high ratings to increased responsiveness to the public; increased emphasis on noncommodity uses; workforce diversification; better working conditions, communications, and openness; and increased environmental sensitivity and awareness. However, the single most important change needed was one of the same ones: increased emphasis on noncommodity uses and decreased emphasis on commodities. The authors stated that the "vast majority of FS employees, both line and staff, feel the agency's policies have changed over the past 10 years. The vast majority see the agency headed in the right direction. However, they also feel the FS still has further to go."

Implications for Ecosystem Management

Discussions about ecosystem management clearly take place in a broad context; the role of the Federal Government, society's values about endangered species, and rights associated with private lands are all being actively debated. Although often stated as jobs versus the environment, commodities versus amenities, or species versus trees, the issues actually represent differing values regarding what benefits society should receive from public lands. Values are really the subject of debate, not just ecosystem management. Understanding and addressing people's values adequately is key to public and agency acceptance of ecosystem management.

Although people express concern about public land management, they look to science to provide many answers and seem willing to trust credible analyses of existing conditions and potential cures and results of scientific study of ecosystems. There are, however, varying levels of trust in scientists employed by different institutions. Although it is recognized that science can provide many types of data and analyses, the people and the institutions with management responsibility decide the use of those results. Science provides the information, not the decision. In other words, science is appropriate for describing problems, proposing techniques for resolving them, and measuring the associated impacts and risks. However, the conditions to be achieved are not decided by science, but are political decisions based on values. Ecosystem management's explicit attempt to blend science and values is both its strength and greatest challenge.



Survey research can help identify barriers to public acceptance of ecosystem management. For example, support for salmon recovery and a willingness to accept resulting socioeconomic impacts seem to be stronger than for endangered species in general. However, most people perceive that the major barriers to salmon recovery are dams and overfishing, rather than lack of suitable habitat. Given this perception, measures that just improve habitat on public lands may be viewed as ineffective and opposed by many if the impacts are perceived as too great.

Defining public lands in public terms such as sense of place, as well as scientific terms, has many advantages. First, incorporating human definitions and meanings about public lands into day-to-day management activities reflects that people are part of the ecosystem. Second, the process of defining and mapping places serves as a new and valuable way of seeking knowledge from the public in a systematic manner. Defining places and their meanings at a community scale extends well beyond traditional forms of public involvement (Williams 1995). Third, considering place in management activities could result in implementation of activities that are more acceptable and more easily communicated in terms that people understand.

Implementing ecosystem management involves continuous learning about people, their attitudes, beliefs, and values. Learning more about people's perceptions of public land and natural resource management and the reasons for those perceptions is a cornerstone of ecosystem management that explicitly includes people, as noted in the *Framework for Ecosystem Management in the Interior Columbia Basin* (Haynes and others 1996). Only a few relevant values are discussed here, which for some affected populations is just a start. People's tastes and preferences change, their perspectives on natural resources are influenced by knowledge, and their acceptance of differing management practices may shift as experience is gained with ecosystem management. One important way that ecosystem management integrates attitudes, beliefs, and values is in describing desired conditions. Development of ecosystem management alternatives requires developing alternative visions of social, physical, biological, and economic conditions that are desirable, and/or alternative ways of achieving those conditions.

Scientific research will improve managers' understanding of the values and interests that may be either adversely affected or positively enhanced by specific actions. Science enhances this understanding by providing a test for the acceptance of practices and the effectiveness related to various techniques, including public participation. Just as science plays an important role in helping to understand biophysical processes, science also has an important function in explaining the social and cultural aspects of decisions.

AMERICAN INDIAN PEOPLES: THEIR PLACE IN ECOSYSTEMS AND THEIR ROLE IN ECOSYSTEM STRATEGIES

The discussion of American Indians in the Basin focuses on their relationships with the natural environment and the trends regarding agency relations with the Basin's affected American Indian tribes. These topics have particular significance for Federal land managers for two reasons: (1) FS and BLM management actions affect resources and areas of concern to American Indians; and (2) the Federal Government holds certain trust responsibilities and obligations to tribes based on various legal agreements, including treaties, which have implications for ecosystem management. Although many ecosystem management issues are common to American Indians and the general public, the legal status of American Indians, the sovereignty of tribal governments, the nature of reserved tribal rights, and the unique concerns of tribes merit separate attention.

As members of both our collective society and frequently also of an Indian society, Native American peoples are well known to their neighbors. As described earlier in this chapter, American Indians comprise a higher proportion of the total population within the Basin (2.5 percent) than of the national population (just less than 1 percent). These populations are not evenly distributed across the Basin, but tend to be located either in association with Indian reservations or with large urban centers such as Boise, Idaho and Spokane, Washington (map 7.2).

There are 22 federally recognized tribes and numerous off-reservation traditional Indian communities whose aboriginal territories or reserved treaty rights are within the assessment area. Traditional Indian communities are communities either under the jurisdiction of a tribe or with cultural affiliations to one or more tribes and therefore lack federal recognition. An Indian person may be an enrolled member of a federally recognized tribe from the Basin or elsewhere, a member of a non-federally recognized traditional community, or someone with Indian lineage cultural ties to the Basin. For many Indian people, self-identity is based on familial ties and other associations that often include a large number of extended family relations. Such family connections provide socially acknowledged individual roles and the social cohesion that typically characterize tribal and traditional community life in the Basin.

Cultural History

Prior to non-Indian arrivals in the region, Basin peoples had successfully resided here for at least 12,000 years. Their cultures permitted adaptation to changing climates, environments, species distributions, and socio-political circumstances. Settlements were distributed across the region, each a member of a diverse array of indigenous cultures.

Map 7.2 - Indian reservations in the Basin.

The political autonomy of these communities and their relatively loose organizational structures meant that primary collective identity was based on village associations, shared lands, kinship ties, linguistic affiliations, and integrative political and economic systems.

Larger groupings of native peoples were later established by researchers based on shared cultural traits and language groups (families). Basin culture areas include the Plateau, which encompasses the Basin's northern half; and the Great Basin, which covers much of the Basin's southern half and a small area of California located just south of the assessment area's southwest corner. Language families included Sahaptin, Shoshonean, Paiute, Kootenai, Interior Salish, Chinookan, Lutumian, Pit River, and Shasta. Although these cultural groupings reflect and hold static the conditions that existed just before non-Indian contact, their influence extends into modern times and serves to bind certain tribes together.

Major population losses, due to introduced European diseases and then relocation of Indian nations onto reservations in the 19th and early 20th centuries, resulted in geographically isolated and distinct rural communities. These newly created communities were formed under federally imposed political structures called "tribes" and consisted of one or more Indian nations. Some federally recognized tribes, such as the Nez Perce and the Spokane, had to settle on a small area of their homelands. Other tribes had to share a reservation in a portion of their homeland with other Indian peoples, including some who may have been traditionally hostile, such as the Confederated Tribes of the Warm Springs and the Wind River Reservation. In other cases, Indian nations (such as the Kootenai, Paiute, Bannock and Shoshoni) were formally separated onto more than one reservation, usually in a small area of their homeland.

History of Legal Standing

Most American Indian tribes and bands were independent and self-governing societies long before their contact with non-Indian peoples or relations with the Federal Government. However, the degree and kind of socio-political organization varied. Consistently, first by European nations and later by the Federal Government, Indian nations have been formally recognized as distinct and independent political communities qualified to exercise powers of self-government by reason of their original sovereignty (Cohen 1971).

The relationship of the Federal Government with American Indian tribes is based on legal agreements between sovereign nations, federal recognition of their dependent sovereign status, principles of jurisprudence, international law, prevailing views of society, and government policies toward American Indians. The body of this formal relationship involves the whole span of United States history, ties with European culture, and conventions in law.

The United States inherited from England two important, albeit conflicting, policies that recognized Indian sovereignty within the context of the "right of discovery" concept, giving title to the discoverer, and made that title subject to Indian peoples' "right of occupancy." These policies are reflected in early documents. The Northwest Ordinance of 1787 (1 Stat. 50) reaffirmed federal recognition of Indian nations' sovereignty, as did the U.S. Constitution. Both policies also stipulated that only the Federal Government could negotiate treaties for cession of lands.

A series of Indian trade and intercourse acts, initiated in 1790 (1 Stat. 137) and permanently adopted in 1834, became the cornerstone of Federal Indian policy. Another significant early contribution to Indian law, known as the Marshall Trilogy, involved three Supreme Court decisions [*Johnson v. M'Intosh* (1823), *Cherokee Nation v. Georgia* (1831), and *Worcester v.*

Georgia (1832)]. These decisions established that: (1) only the Federal Government has the preemptive right to procure Indian land; (2) the Federal Government has trust responsibilities toward American Indian tribes; and (3) treaties take precedence over state law.

Treaty-Making Period

When the Oregon Territory was created in 1848, provisions of the Northwest Ordinance were extended to the new territory, confirming Indian title to land and recognizing lands not expressly ceded to the United States by ratified treaty or agreement as Indian Country. Soon after, an aggressive policy of securing land for non-Indian settlers motivated treaty-making efforts west of the Cascade Mountains. However, the Oregon Donation Act in 1850 provided patents (7,437 claims in Oregon and 1,018 in Washington) to land totaling 2.8 million acres to new settlers of the Territory prior to ratification of any Pacific Northwest treaties for tribal land cessions. This action, taken contrary to established United States policy, created considerable tension in the region.

The period between 1840 and 1870 was one of increasing tension between Indians and non-Indians in the region for a variety of reasons: large and dramatic declines in Indian populations due to recurring epidemics; non-ratification of Indian treaties negotiated with western Oregon tribes in 1851; encroachment upon and seizure of Indian lands authorized by territorial leaders and Congressional acts despite legal agreements with tribes; rapid loss of access to and destruction of Indian food resources; and persistent antipathy toward, and mutual fear between, both societies (Beckham 1984).

Treaties with Indian nations of the region sometimes addressed the United States' interest to maintain peaceful relations and to secure rights to travel through Indian lands (Treaty with the Eastern Shoshoni 1863; Treaty between the United States and the Blackfoot Nation of Indians 1865). The purpose of other treaties was more comprehensive and addressed land title status, creation of reservations, and Federal obligations to tribes.

In 1855, some Indian nations within the Basin entered into treaties with Isaac Stevens, then Governor and Superintendent of Indian Affairs for Washington. These ratified treaties provided for apportionment of land and natural resources and still serve that purpose today. Tribes affected by these treaties include the Confederated Tribes of the Colville and the Umatilla reservations; Confederated Tribes and Bands of the Yakama Nation, Nez Perce Tribe; Kootenai Tribe of Idaho; and the Salish and Kootenai Tribes of the Flathead Reservation. The Blackfeet Tribe, located adjacent to the assessment area boundary, also made treaties with Governor Stevens in 1855. These various treaties contain similar language reserving tribes' existing rights, such as this example from the Flathead:

> *The exclusive right of taking fish in all the streams running through or bordering said reservation is further secured to said Indians; as also the right of taking fish at all usual and accustomed places, in common with citizens of the Territory, and of erecting temporary buildings for curing; together with the privilege of hunting, gathering roots and berries, and pasturing their horses and cattle upon open and unclaimed land.*

In other Basin treaties and agreements, similar preexisting tribal rights were recognized, such as the right to access and use water sources, trap animals, cut and gather noncommercial wood, or engage in water power uses. While the scope and intent of the Stevens' treaties concerning rights to fish at all usual and accustomed stations and grounds in common with citizens of the Territory has been addressed through numerous court decisions, the geographical limits on other treaty-reserved rights have remained largely unexplored. Such terms in legal documents as "open," "unclaimed," "public lands," and "unoccupied" lands carry the implied condition that rights reserved on such lands could be exercised until the lands were closed, claimed, or occupied by United States citizens under the public land disposal statutes.

Lands ceded by treaty to the United States were typically delineated by non-Indians and were not accurate representations of tribal homeland areas;

customary land-uses routinely extended beyond the homelands of any particular Indian group. These reserved rights and treaty obligations are a significant factor in public land management. Tribes and traditional Indian communities have areas of interest that are based on prehistoric and historic land-use patterns; these extend beyond reservations boundaries and also often extend beyond lands that tribes ceded to the United States.

The explicit reservation of rights through treaty constitutes an assurance by the Federal Government that traditional lifeway-based land uses can be sustained. What is reserved are the activities that support an Indian community's way of life, not simply a resource use (Hunn 1990). Through historic legal agreements, tribes received promises of Federal protection for their lands, resources, and people. These promises constitute fiduciary responsibilities, also called trust responsibilities and obligations. Considerable benefits were gained by the Federal Government by establishing legal rights to Indian lands and providing a basis for economic, political, and social development in the Northwest.

Development of Federal Indian Policy

For more than two centuries, Federal policy toward Indian peoples has vacillated between two conflicting themes: (1) self-determination and an acceptance of cultural plurality; and (2) assimilation of Indian peoples into American culture and weakening of tribal governments. For example, those reservations set aside by treaty, executive order, or agreement, though sizable in the beginning, were systematically and significantly reduced in area as a policy of reservation consolidation and reduction prevailed between 1871 and 1928.

Passage of the Dawes Act in 1887 (24 Stat. 389) led to dramatic reductions in tribally owned lands, if not elimination of reservations in some cases. "Surplus" lands were identified on reservations and allotment plans were developed and implemented over the next few decades, leaving tribes dispossessed of much of their lands (Cohen 1971). Nationally, tribes lost 90 million acres, from 138 million acres down to 48 million acres, and the remaining Indian Country was severely fragmented. Effects of this Act and the allotment policy can be seen in the land ownership patterns of many reservations.

The allotment process was terminated in 1934 with a basic shift in policy away from forced assimilation to one of cultural and ethnic pluralism. The Indian Reorganization Act of 1934 (48 Stat. 984) provided an opportunity for tribes to adopt provisions for self-determination. The Act facilitated major revisions to federal policy by ending the allotting of Indian lands, extending the trust status to lands allotted, restoring unsold "surplus" lands from the allotment period to tribal ownership, ceasing the sale of Indian lands to non-Indians, promoting acquisition of lands for Indian use, establishing tribal enterprises, encouraging tribes to incorporate, providing revolving loans, and enhancing management practices for Indian forests and range (Cohen 1971).

This policy sought to promote reservation autonomy and self-determination and to preserve Indian cultures and values. For example, under the Indian Reorganization Act, the Quartz Valley Indian Community was established; also, the Fort McDermitt Paiute Tribe received economic assistance, allowing a grazing cooperative for tribal members to be developed through the Bureau of Indian Affairs. Although many Basin tribes accepted the Act and its provisions, some were not receptive due to concern about possible adverse effects to their legal rights and interests.

The Act fostered changes in many Basin tribal governmental structures. Constitutions and bylaws were adopted by tribal members and approved by the Secretary of the Department of Interior. These written laws were then implemented by elected officials who replaced the traditional tribal headmen or recognized chiefs. Elected councils were responsible for establishing economic development and resource management policies for reservation timber, rangeland, and farm lands.

The period between 1943 and 1961 marked another era of major changes and setbacks for tribes. With the Termination Act of 1953, a forced assimilation policy was again introduced. Reservations of selected tribes were terminated and lands sold, often to third parties. Federal recognition and services to these tribes ceased, and tribal sovereignty was terminated.

Often, however, much more was forfeited through the termination process. The Klamath Tribes, one of the Basin tribes affected, lost its federal recognition and its land base; their land base subsequently became the eastern portion of the Winema National Forest. The Quartz Valley Indian Community and the Northwest Band of Shoshoni Tribes were other Basin tribes terminated under this Act. Subsequently, all three tribes have been reinstated as federally recognized tribes. However, as for most tribes targeted for termination, effects on community and social well-being are ongoing. Little of their lost land base has been recovered, and the tribes are struggling to re-establish their governmental organizations and economic self-sufficiency to provide needed services for their members.

By the early 1970s, the termination policy had been rejected and was being replaced by one that promoted a renewal of tribal self-determination. Tribal communities across the Nation greatly benefited from actions of the Nixon administration that resulted in the Self-Determination and Education Assistance Act of 1975 (88 Stat. 2203). The Act provided substantial funding avenues for the tribes and granted authority for tribes to acquire lands adjacent to reservations. The Act also enabled tribes to pursue economic growth and to effectively assert a political role in the region.

Indian Case Law and Federal Administrative Policy

As tribes developed sophistication in dealing with states and Federal agencies, moving away from Bureau of Indian Affairs' domination in tribal government operations, they began to address issues relating to their legal interest and cultural relationship with natural resources; this sometimes involved lengthy and controversial court cases. The interpretation of tribal rights and property interests and the nature of the tribes' legal relations with state and federal agencies have developed into a large body of Indian law. Cases involving Basin tribes, dating from the late 1800s, often revolve around interpretations of treaty-reserved fishing rights.

One early Supreme Court case, *United States v. Winans*, 198 U.S. 381 (1905), addressed the right of Yakama tribal fishermen to fish at a well-known usual and accustomed fishing station when their access had been effectively denied by construction of a commercial fishing operation. In this case, the court's opinion stated in part:

> *...the treaty was not a grant of rights to the Indians, but a grant of rights from them - a reservation of those [rights] not granted [away to the United States government]...*
> *The contingency of future ownership of the lands, therefore, was foreseen and provided for—in other words, the Indians were given a right in the land—the right of crossing it to the river—the right to occupy it to the extent and for the purpose mentioned [such as fishing].*

The implied right of access to usual and accustomed fishing places extends to both private and public lands. In 1974, a U.S. Washington District Court (upheld by the Supreme Court in 1979) reaffirmed off-reservation fishing rights and their priority over other uses. Tribes were allowed up to a 50 percent share of harvestable fish passing by accustomed traditional fishing places. That case also recognized the sovereign right of tribes, rather than States, to regulate their off-reservation treaty rights. States regulate tribal use for conservation purposes only. An important aspect of this decision is the surmised right of tribes to take part in the protection of fish habitats and to help ensure that the resource persists and in quantities available for fishing. The case has been allowed to stand open, as does the similar *United States* v. *Oregon* case that began in the late 1960s, to resolve other disputes concerning exercise of treaty-reserved rights.

Numerous Federal regulatory acts passed in recent decades have increased the roles of tribes in public land management decision-making processes. These acts include:

- National Environmental Policy Act of 1969 (NEPA) (83 Stat. 852).
- American Indian Religious Freedom Act of 1978 (AIRFA) (92 Stat. 469).
- Archeological Resources Protection Act of 1979 (ARPA) (93 Stat. 721).
- Native American Graves Protection and Repatriation Act of 1990 (NAGPRA) (104 Stat. 3048).
- National Historic Preservation Act of 1966 (NHPA) (80 Stat. 915) as amended in 1992.
- Religious Freedom Restoration Act of 1993 (107 Stat. 1488).
- 1994 amendments to the Self-Determination and Education Assistance Act of 1975 (108 Stat. 4272).

The portion of case law pertaining to off-reservation tribal interests and federal agency land management is reflected in recent federal administrative policy and guidance. Interior Secretarial Order No. 3175, issued in November 1993, requires all bureaus and agencies to conduct trust responsibilities of the Federal Government, assess the impacts of their actions on Indian trust resources, and consult with tribes when impacts are identified. A White House memorandum issued in April 1994 emphasized the importance of government-to-government relations with tribal governments and the need to consult tribes prior to taking actions that may affect tribal interests.

The close of the 20th century bears witness to an extended period of increasing tribal political and economic involvement in mainstream regional society. Recent Congressional acts, executive orders, and federal court decisions have provided a basis for tribal renewal. The region's tribes have become active in seeking cooperative opportunities with states, federal agencies, and private landowners to address shared concerns about ecosystem issues and specific resource strategies. In keeping with each tribe's unique legal and cultural history, Indian people are forging individual paths toward socioeconomic development. The Federal Government is responsible for assisting tribes while still recognizing their sovereign standing.

The trust relationship between the U.S. Government and Indian Tribes is a part of the very fabric of federal Indian law. There are stringent fiduciary standards of conduct imposed on federal agencies in their relationships with Indian Tribes and Indian-owned assets. Meeting the Federal Government's trust responsibility is consistent with, although not the same as, meeting Federal obligations to all users, which are to protect and restore habitat necessary to maintain resources at healthy, sustainable, usable levels for present and future generations.

Place in Basin Ecosystems

The intense interest of Indian peoples and their tribal governments in the region's ecosystems and natural resources is founded in their long-term relationship and spiritual attachment to the land. Although many differences exist among the region's Indian communities, the various tribes hold a common belief about their relationship with the land and water (Dick 1990). All tribes understand that placement of their peoples in this landscape was by the Creator. Therefore, the Indian ancestry in the Basin extends from "time immemorial," a long-term attachment reflected in modern Indian culture.

Indian peoples are part of a large, loose social web strengthened by their shared experience of the Basin and associated ecosystems (Hunn 1990). Traditional subsistence economies were broadbased and included fishing, fowling, hunting, trapping, livestock grazing, and gathering of terrestrial and aquatic resources over very large geographic areas and a diverse range of important places (Walker 1993). The full range of resources needed to sustain families and Indian cultures was found in the socially and culturally important

ethno-environments and ethno-habitats of their homelands and traditional use areas. Living cultural traditions are embedded in these older understandings of the land, resources, landforms, ethno-habitats, and landscapes. Consequently, Indian peoples have accrued a "detailed, encyclopedic knowledge of their environment" through the millennia (Hunn 1990).

The intimacy and length of attachment to the land and the totality of landscape importance have contributed to a strong sense of place for Indian peoples. Lands sacred to Indian peoples and all the natural components of such lands participate together in a system of complex interrelationships. As such, places of significance are created by an intersection of natural systems, cultural uses, social systems, and cultural meanings. Knowledge of places is passed to each succeeding generation through oral storytelling, various performed rituals, and personal experiences. The importance of cultural places is embedded in the regional, although now somewhat melded, Indian cultures of the Basin. This "symbolic link" to the land is the context for maintaining community and cultural identity.

The world view of tribal communities is complex and includes both traditional native values and belief systems along with common Christian-American values. In general, traditional community values assert an interconnected natural world that includes people and the important interactions between Indian people and the land. Indian peoples may consider themselves caretakers of the lands, especially within their homelands, seeking protection of all resources (natural and cultural) and recognizing their collective significance.

Traditional peoples typically feel privileged to be able to eat native foods, be respectful of the Creator, enjoy the bounty of a diverse natural world, and listen to their elders and their teachings. In traditional belief systems, all life in the ecosystem shares the world's past existence and, with people, has intelligence and possesses moral rights and obligations. The benefits of a balanced and moral human society are extended to the entire local ecosystem.

Today, as in the distant past, tribal members and their governments hold considerable natural resource information in the form of both academic (many tribes employ resource professionals) and "indigenous" knowledge (DeWalt 1994). Elders have kept traditions alive through the practice of traditional culture and their counsel to younger generations. Besides providing cultural continuity and a form of sustenance and comfort for those who follow the traditional ways, these traditions help to sustain social cohesion and well-being. This extensive knowledge base is beginning to gain consideration in public land management, in part as a means to consider American Indian interests and public land-use needs.

American Indian cultural values toward public lands have tended to be subsumed under general categories, such as nonconsumptive or recreational land uses as understood for the general public. The primary cultural activities commonly include harvest of natural resources and associated activities: fishing, hunting, noncommercial wood cutting, gathering, resource processing, scouting for ethno-habitats and camping. Other public land-uses include religious practices or observances such as spirit quests, visiting unmarked graves, rites of passage, livestock grazing, and cultural tours.

Many American Indian cultural uses (such as camping, wildlife viewing, hunting, fishing, and berry picking) follow use patterns similar to recreational uses for the general public. However, differences in the purposes and social context (how such uses contribute to community social well-being and cultural integrity) often distinguish them. Resource acquisition activities such as fishing, hunting, and plant and mineral gathering are usually done within the context of traditional socio-cultural and economic systems. For many Basin tribes, a series of spring and summer root, salmon, and berry feasts mark high points on Indian religious calendars (Hunn 1990). In addition to these substantial feasts, numerous other occasions and events occur throughout the year

(often held in community longhouses, shorthouses, Indian Shaker churches, or private homes) that are supplied with traditional foods. These native foods are usually collected from a tribe's or traditional community's ethno-environment (area of interest or homeland) and its socially and/or traditionally significant ecological places (ethno-habitats), typically on reservations or public lands.

In 1805, Lewis and Clark observed that thanks were ritually offered to the first spring Chinook by the whole community (Spier and Sapir 1930). The mixture of religious, social, subsistence, and economic values for a variety of aquatic and terrestrial resources found then continues today. The degree that individuals and families participate in this lifeway often brings them esteem from the community and generally acts to provide cultural continuity, social cohesion, and individual well-being. Cultural relationships with aquatic species are reflected in the folk taxonomy and nomenclature of Sahaptin speakers, who classify fish on the basis of both their physical attributes and their Indian cultural uses (Hunn 1990). Fish, such as the Pacific lamprey and sculpin, while of little interest in American society, are still desired and respected by Indian peoples. Living cultural traditions in the Basin are exemplified by the fishing done from wooden platforms with dip nets just below The Dalles Dam on the Columbia River or on southern Washington's Klickitat River, and the traditional gaff-hooking at fishing stations on the John Day River and Catherine Creek in Oregon.

People's diets have become largely supplemented with other foodstuffs from American culture, but native game animals are still very much desired and consumed. Hunting as an activity also serves a greater socio-cultural role. For example, the taking of a youth's first game animal becomes the focus of a rite of passage in many tribes. Leadership roles may be aligned in traditional religious arenas based on the knowledge, skill, and proficiency of men who hunt for their communities.

In the past, principal meat sources were derived from wildlife, including deer, pronghorn, bighorn sheep, moose, elk, bison, bear, rabbit, and groundhog. These and other animals may still be considered powerful and able to help or hinder a person's ability to progress through life. The power to cure diseases often comes from animal spirits (Fowler 1986). Their importance in diet, economy, or religion varied by culture and was influenced in part by the natural range and population density of a species and people's cultural values for them.

Non-Indian fish and game laws may sometimes be viewed as meshing well with traditional Indian laws that prescribe the respectful taking of game life. At other times, when considering a man's community or family obligations and his right to exercise aboriginal and/or treaty-reserved rights, they mesh poorly. At times throughout this century, there have been public misunderstandings concerning tribal takings of fish and wildlife, which have resulted in complex and extensive Federal court adjudications in recent decades.

The importance of native plants has received relatively little recognition compared to other native resources. Yet, use of plant resources as food during the ethno-historic period was at least equal to, if not greater than, use of fisheries (Hunn 1990, Fowler 1986). In fact, food-plant resource locations, not fishery ethno-habitats, have been considered the critical variable for determining the placement of historic settlements in the Nez Perce region (Ames and Marshal 1980).

Plants and their communities and habitats continue to be valued. Plant parts are used for purification, ceremonial, subsistence, commercial, and medicinal purposes and for creating objects of personal use, trade, gift-giving, or sale (Fowler 1990, Schlick 1994, Wilke 1988). Plants play special roles in the physical and spiritual cleansing or purifying of a person, and may be found at various life-event ceremonies including daily sweats, funerals, and disciplinary actions. Like fish, plants are used commercially and for subsistence, ceremony, and trade.

Traditional use of plants reflects the resilience and persistence of common cultural themes in the Basin (Hanes 1982, Hunn 1990). In recent years, there has been renewed interest in traditional plant use by Indian people in parts of the Basin. Such an interest is seen as socially rewarding and important for maintenance of traditional activities, which provide cultural continuity and reaffirm Indian identity (Coulture and others 1986). For some Indian families and tribes, the practices and relationships associated with plants and plant ethnohabitats have continued unabated throughout this century.

Some plants identified by the ICBEMP as of tribal interest are characterized as habitat generalists and are associated with terrestrial community types found widely distributed in the Basin. However, plants are considered significant in a given culture on the basis of people's recognition of the plants and the values and/or uses assigned to the plants. As a result, many plant species are more significant than may be recognized by either the native folk biologist or American naturalist. For example, a plant such as camas may be known to live in several habitat types, but the plant normally occurs in the quality and quantity appropriate for harvest in only a few of those types. Also, a plant may occur in abundance in one tribe's area of interest. Though considered highly valued by a second tribe, the plant may not be valued in the same way, or to the same degree in the two different cultures.

Cultural activities occur frequently outside the purview of both the public and the land managers. The public's understanding of cultural plants or any competition for them has been restricted to a few plants, such as huckleberries, morel mushrooms, or beargrass. As a consequence, some plant ethnohabitats have not been recognized or valued in a shared way by the general society or the tribes.

Scablands are one example, with their characteristic areas of shallow rocky soils, sometimes interspersed with large mounds of deep soils. Agencies have often dismissed scablands as non-productive timber lands with limited range values, and even considered them unattractive or desert-like. Scablands have been used as convenient road locations or borrow pit sources. Most Basin tribes have a very different perception; to them, scablands are places high in biomass, which produce highly valued foods that are part of the traditional springtime focus in Indian life.

The cultural significance of the environment is much more complex than simply a source for food or medicine. It involves social values and meanings that interlace traditional societal, political, religious, and economic areas of modern native cultures (Hunn 1981). The culturally familiar natural world and its life forms support individual, family, community, tribal, and regional Indian identity, socioeconomic well-being, and quality of life.

Like most traditional societies, Indian communities have preserved a well-established tradition of close-knit groups. Individuals are recognized through kinship ties and roles, usually in the context of extended family structures. In general, communally controlled uses of lands and resources have evolved over the past century. For some tribes, such uses were greatly altered during the allotment policy period, when families and lands were separated into discrete areas across Indian Country. For those lands remaining in tribal ownership (not privately held), tribal laws and traditional laws prevail. On public lands still visited by traditionalists, communal values and traditional laws commonly dictate appropriate resource uses in addition to tribal, state, and federal laws.

Community health is affected by numerous factors, including economic opportunity; pursuit of traditional uses of the land; effective trust relationships with the Federal Government; and freedom to practice cultural, religious, and social customs. Shortfalls in any of these factors can potentially lead to various effects on the well-being of Indian communities. Accumulative, and at times substantial, adverse effects have been observed in the social history of Basin tribes. These effects have been reflected generally in social measures such as family cohesion, drug and alcohol abuse, depression, low self-esteem, suicide rates, crime, and physical health.

Implications for Ecosystem Management

In casual conversation and in substantial tribal government expenditures, the natural biophysical world still pervades Indian life. The continuance of American Indian/tribal land-based lifeways and Indian people's dependence on natural resources are expected to draw multiple Federal land management agencies into dialogue with affected tribes well into the future.

Tribal governments have an increasing influence on the formulation of public land policy because of their legally reserved and established rights, as well as their unique trust relationship with the United States Government. In recent years, there has been an increased understanding of the sovereign status of tribes and an increase in government-to-government relations between tribes and agencies. This has resulted in increased participation by tribes in all agency planning levels (policy, program, and project) as a consultation strategy. Also important are early involvement in project planning and opportunities to contribute to implementation and monitoring stages of projects.

Agency decision-makers should be familiar with potential effects on tribal interests and rights early in the planning process. Federal agencies are obligated to use their authority in safeguarding tribes' reserved rights and trust properties that are under their jurisdiction. Federal agencies cannot renegotiate or narrowly interpret the historic agreements between the Federal Government and tribes either in the consultation process, or through management decisions and actions.

Recognition of the uniqueness of each tribe has placed the burden on agencies to become knowledgeable of, and sensitive to, Indian interests on an individual tribal basis. There is great variation in demographic characteristics, and the nature of rights, interests, and dependence on public land resources between tribes. One implication is that an ongoing dialogue would benefit agency-tribal relations if established locally, over and beyond the notification and consultation requirements associated with NFMA, NEPA, NHPA, ARPA, NAGPRA, and other regulatory acts. Frequently, agencies have communicated with tribes largely in the context of stringent timeframes derived from statutes that apply to agency undertakings, rather than in desirable tribal consultation processes.

In addition, with passage of the Self-Governance Act late in 1994, increased emphasis is being placed on involving tribes in Federal management processes, including development and implementation of land-use plans, preparation of budget proposals, and conducting of other activities on public lands on behalf of the agencies. Tribes also now have the option of considering the incorporation of programs or functions (otherwise under federal agencies) into their tribal responsibilities if they are interested and can provide justification.

Use of the "ecosystems" concept essentially serves as a social "tool for holistic and empathetic thinking about nature," which takes into account the culturally based perceptions of science and society toward landscapes (Ingerson 1994). Whereas "science" is based on observable elements and processes of nature visible to anyone, the nature, significance, and importance of Basin landscapes for Indian peoples are prescribed by the full benefit of cultural systems and values. The natural world is "sacred" and seen in a manner that is both physical and spiritual, not subordinate to, nor dependent on, scientific analysis. Federal agencies consider the natural world in a linear way, with decision-making that relies on traditional hierarchial and compartmentalized thinking.

One implication of differing world views between agencies and tribes is that agency data collections are commonly performed in the language of natural or social scientists, which may not sufficiently accommodate the general complexity of human behavior or differing cultural world views and sensibilities. An important element in efforts to address these differences is maintenance of meaningful and ongoing dialogue. Ecosystem management provides a sound framework for incorporating traditional environmental knowledge into decision making, but the mechanism for accomplishing this needs to be developed.

Meaningful dialogue through an effective consultation process is an important issue among tribes. Consultation among federal agencies, tribes, and American Indian communities has its basis in Federal law, court interpretations, and executive orders. Consultation is not a single event, but a process that leads to a decision; consultation serves at least four purposes:

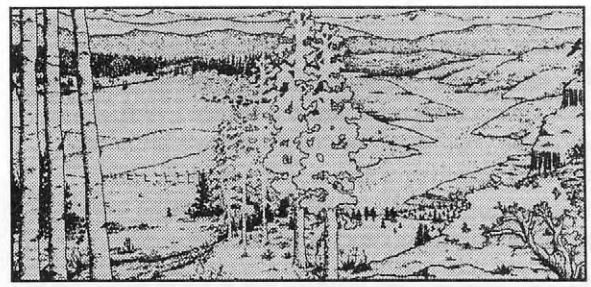
- Identify and clarify the issues.
- Provide for an exchange of existing information and identify where information is needed.
- Identify and serve as a process for conflict resolution.
- Provide an opportunity to discuss and explain the decision.

Consultation means different things to different tribes; it can be a formal process of negotiation, cooperation, and policy-level decision-making between tribal governments and the Federal Government, or a more informal process. Consultation can be viewed as an ongoing relationship between one or more agencies and one or more tribes characterized by consensus-seeking approaches to reach mutual understanding and resolve issues. It may concern issues and actions that could affect the government's trust responsibilities or other tribal interests. Developing a consistent approach to consultation that meets tribal needs is one of the challenges of ecosystem management.

The ongoing nature of consultation suggests that it is not appropriate to solve the issues of treaty rights by providing American Indians with sufficient land, resources, and access to sacred sites, with the assumption that the problem will then go away. Many tribal issues are based upon tribal needs, interests, and rights, which are taken from their histories, living cultural traditions, and modern lifeways. As agencies seek to consider and accommodate human needs in land management decisions, an understanding of the shared and unique relationships that both tribes and the general public have with landscapes will emerge. Ecosystem-appropriate decisions in land management would tend to follow from including these human values and cultural rules.

As agencies recognize that American Indians use places and resources largely because they are among those limited number of places and ethnohabitats shown and interpreted to them by elder relatives, land management may be able to better prioritize and meaningfully consider American Indian needs. Similarly, as agencies incorporate this understanding with tribal interests in healthy ecosystems, and the restoration or conservation of ethno-environments and habitats, apparent conflicts and lingering frustrations may be resolved.

Fundamentally, tribal governments and traditionalists have a well-established history of compromise and acceptance of changes to their homelands, even when changes have affected those places and aspects of their lifeways of most significance. American Indians struggle with many of the same issues in today's society that others face. As described by Bordewich (1996):



> *The Indian story does not end, of course, with an intellectual accommodation with the past or even a moral coming of terms. Indeed, the story does not end at all. Until now each age has imagined its own Indian: untamable savage, child of Nature, steward of the earth, the white man's ultimate victim. Imagining that we see the Indian, we have often seen little more than a warped reflection of ourselves; when the Indians have stepped from the roles to which we have assigned them, we have often seen nothing at all. There will be not an end to history, but an end may be put to the invention of distorting myth. With that may come the recognition that Indians are not, at last, poignant vestiges of a lost age, but men and women of our own time, struggling to solve twentieth-century problems with tools of our shared civilization. To see Indians as they are is to see not only a far richer tapestry of life than our fantasies ever allowed but also the limitations of futile attempts to remake one another by force. Stripped of myth, the relationship between Indians and other Americans may yet remain an uncertain one, an embrace that permits neither consummation nor release, but that is, nonetheless, full of hope.*

COMMUNITIES: FROM DEPENDENCY TO RESILIENCY

Social and economic transformations that have characterized the Nation for the last two decades are particularly striking in the Basin because they are a stark contrast to traditional images of the American West. Technological advances, a growing population, improved transportation systems, and an ever-expanding set of global relationships lead to visible changes in the everyday lives of people in the Basin. Where there were saw shops there are now espresso bars; mountain bikes have replaced locomotives on old railroad grades; and recreational vehicles, not logging trucks, clog the roads. The overarching character of the Basin remains rural, however, with a population residing within a natural environment that, in a comparative sense, retains much of its original quality. Environmental issues, many of which are intertwined with the central social changes occurring nationally, confront the region's citizens directly on a daily basis. These issues also affect people living elsewhere that benefit from the natural resources and values in the Basin.

Change is intrinsic in both biophysical and human systems, and many changes in environmental policy result from shifts in public preferences for managing the environment. Rural communities in the Basin have been linked traditionally to natural resources, giving cause for people to be deeply concerned about what will happen to the places where they live. Concern about the future of rural communities, especially those with high employment in industries that utilize Federal resources, was reflected at a July 5, 1995 Congressional hearing held in Grangeville, Idaho. The Forests and Public Land Management Subcommittee conducted the hearing; its subject, "Endangered Communities," explained the subcommittee's concerns.

A key debate about ecosystem management is the role of the FS and BLM in promoting community well-being. There are questions about how to make tradeoffs when objectives for communities conflict with those for achieving desired conditions of other ecosystem components. There is also a need to know how the agencies can best assist communities in their own unique efforts to achieve and maintain social and economic health. Community well-being as a social goal needs to be better understood in relation to the health of other ecosystem components.

Community Definition and Relation to Ecosystem

The term "community" can have several definitions (Society of American Foresters 1989). Communities can be groups of like-minded people who gain strength from their relationships and associations. Communities of interest, as these groups are called (Sirmon and others 1993), can be people employed in a similar profession, people who participate in the same activities, or those who share a set of values; examples are the ranching

community or the whitewater boating community. People within these communities are linked because of their interests or concerns and may live in a wide variety of locations (Bates 1993). These different communities are important units of analysis for impact assessments because social and economic impacts are unlikely to be evenly distributed across diverse interest groups.

In this chapter, community has a more traditional definition: a spatially defined place such as a town. Community is an important scale for ecosystem assessments because communities are where people socialize, work, shop, and raise their children; communities are the focus of people's social lives. In public meetings conducted by the ICBEMP Science Team and in scoping and other meetings held by the EIS teams, people have repeatedly expressed concern that conditions and functions of communities and related places used and valued by residents be identified and considered alongside other ecosystem components. Although counties are an important political scale to consider, leaving the discussion at that level would mask the many differences among communities within a given county.

The Bureau of Census recognizes 476 communities within the project area, including 29 cities larger than 10,000 in population and 49 Census-Designated Places, which are locations that are unincorporated but have an identity to the local population. Of the other almost 400 small rural communities, 68 percent are communities of 1,500 or less, which is the smallest size class. These communities range in size from 22 to 1,500 people, with an average population of 520.

The Interior Columbia Basin Ecosystem Management Project collected many types of information about Basin communities, particularly the nearly 400 communities with populations less than 10,000. Harris and others (1996) have a complete description of this information, including community self-assessments consisting of interviews with 1,350 community leaders and residents in nearly half of the Basin's communities. In addition, because social and economic conditions in communities are intertwined, a profile of the economic structure of each community was developed (Harris and others 1996).

The following discussion describes Basin communities and their relationships to lands administered by the FS and BLM. It begins with an overview of the types of fundamental socioeconomic changes that Basin communities are experiencing, many of which parallel those occurring in rural areas nationwide. This is followed by a review of law and policy that allow the FS and BLM to address community issues and promote community well-being. Basin communities are then described in terms of their resiliency, which is their ability to effectively respond to change, along with the primary ways that FS and BLM management actions currently affect resiliency.

Economic and Social Changes Affecting Communities

Basin communities are affected by the social, economic, and political trends and conditions occurring in much of North America near the close of the 20th century. Although the history of human interaction with natural resources in the Basin has numerous stories of cultural adaptation to changing conditions, the rate of change has accelerated in the present era. Several changing elements are described below, along with implications for community development, expectations about Federal land management, and community relationships with the natural environment.

As described in the Economic Assessment (chapter 6), the region's economy has experienced significant change over the last three decades. In terms of job production, the Basin's economy has grown much faster than the Nation as a whole, although not quite as fast as the West's overall, while the importance of some industries that manage and extract commodities from the environment has declined over the last 30 years (Krannich and others 1994). For example, Rasker (1993) found that nearly all job growth in the Yellowstone Ecosystem in the period 1970 to 1990 was in industries other than traditional resource commodity sectors.

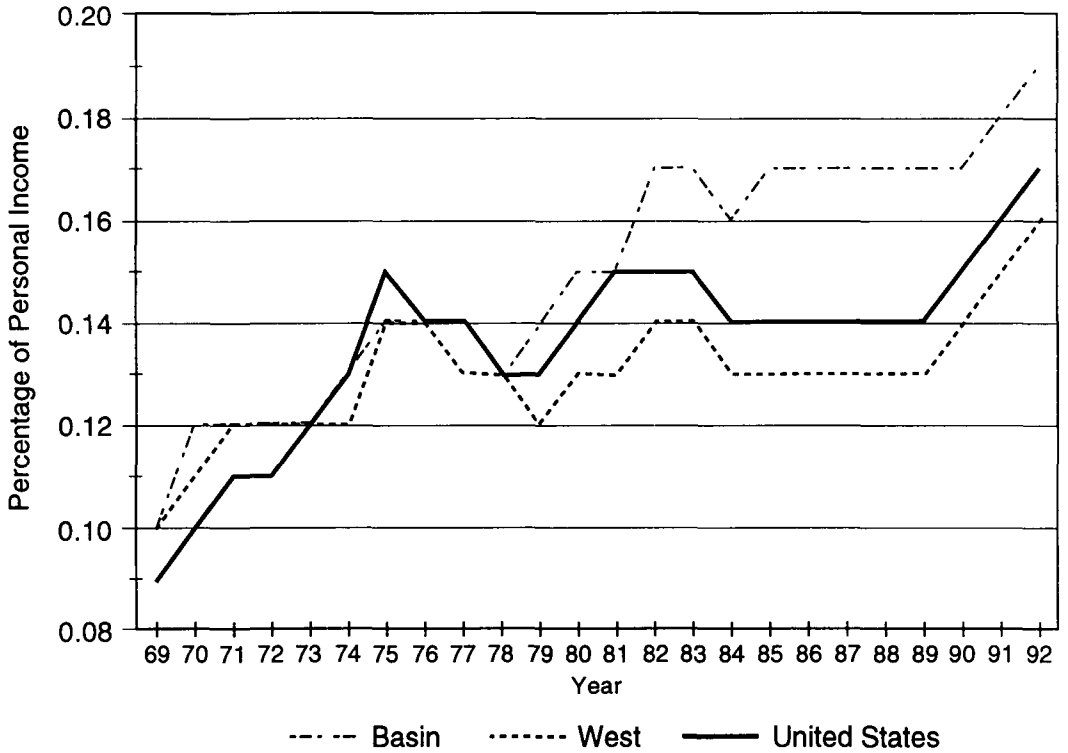

Figure 7.3 - Transfer payments have become increasingly important sources of personal income since the late 1960s. This trend is particularly pronounced in the Basin. (Source: Bureau of Economic Analysis, Regional Economic Information System).

Service industries have become more important at all scales and, along with retail sales, finance, insurance, and real estate, account for 61 percent of the Basin's job growth since 1969. Service industries and people receiving "nonlabor income" in the form of retirement annuities, interest, dividends, and other transfer payments have increased significantly. Figure 7.3 shows how transfer payments have increased in significance since 1969 for the Nation and the West. Although the Basin has followed those trends, the importance of transfer payments varies significantly. Rasker (1993) and Rasker and Glick (1994) suggest that the growth of transfer payments and service sector industries in rural areas is strongly related to environmental quality, an issue explored more thoroughly later in the section on amenities.

Except for urbanization, rural communities in the Basin have been subject to national social-demographic changes (Krannich and others 1994), as have larger cities in the Basin that have also seen increased growth recently. These changes include an older population, migration to smaller communities, increasing diversity of household types, increased poverty, and the shift toward occupations in service industries. Increased population growth from in-migration poses a whole set of challenges to rural communities, as well as to public land management.

There is a growing perception that decisions affecting the viability of local communities tend to be increasingly more remotely located from the community, producing a feeling of powerlessness.

Warren (1978) stated that "local communities are being engulfed by forces which they cannot control...less and less of what goes on locally is subject to the collective decisions of local people." During the latter part of the 20th century, the focus of control for many industrial and retail sectors shifted away from local and rural communities, resulting in increased dominance of nonlocal decision-making in local affairs.

Blatner and others (in press) suggested these trends result "in a double bind in which rural communities appear to be more linked to urban centers for economic survival, yet are being left behind as a result of uneven growth in the global economy." External changes are significant in the sense that they impact people, their communities, and their interactions with the natural environment. These changes are powerful, dynamic, unpredictable, and generally uncontrollable at the local level, although how communities deal with change within their domain is subject to discretion.

The discussion on attitudes, beliefs, and values described many of the expectations of Basin residents and other members of the public for FS and BLM management of public lands. Demographic changes within communities have shifted expectations about forests and ecosystems and their management. That discussion also addresses sense of place and its measurement at the community level. One way communities define themselves is by the places and meanings shared by residents and others who care about the Basin. The social and economic changes discussed above, and their effects on particular pieces of land that people care about, is an important consideration for communities. Attachments to places on public land and the ability to use those places in traditional ways contributes greatly to the quality of life of many Basin residents.

Legal, Policy, and Social Context

The FS and BLM do not have specific legal mandates to improve the health of rural communities, but existing law and policy permits and encourages consideration of economic benefits when planning and implementing Federal actions. The political support for thriving rural communities traces back to Jeffersonian ideals of a democracy based on the independence of "yeoman" farmers. Federal rural policies have a lengthy and complex history of subsidizing farm families. The legislative signals for supporting communities that have traditionally extracted timber is mixed, however, and Federal obligations to rural communities in grazing or timber producing zones of the West remain the subject of political debate.

Use of the National Forests for national and regional growth and development was policy when the Organic Act was passed in 1897 and remains important today. Early policy represented a belief that resources existed for the benefit of the local residents who needed them. Individual uses were determined largely by local demands and needs of users and the larger community living in and near Federal lands. The Forest Service's 1905 "Use Book" listed "protecting local residents from unfair competition in the use of forest and range" as a principal objective of the forest reserves, apparently in response to concern about the influence of big industry. The Bureau of Land Management received a comparatively strong legislative mandate in the Taylor Grazing Act (1934) to stabilize the livestock industry dependent on public range, which also reflects concern for community economic health.

The Sustained Yield Forest Management Act of 1944 linked timber supply to community stability by providing authority to establish cooperative sustained yield units. The purpose of these units was to "promote the stability of forest industries, of employment, of communities, and of taxable forest wealth." Although this concept has been experimented in the Basin, its success has not been demonstrated. The National Forest Management Act of 1976 added substantially to community stability policy by solidifying an even-flow timber supply strategy. Section 14 (e)(1) of NFMA addressed community stability by requiring bidding methods for timber sales to "consider the economic stability of communities whose economies

are dependent on such National Forest materials." In 1977, and again in 1987, the Forest Service developed lists of timber-dependent communities to receive special consideration for bidding on Federal timber sales.

The primary authority for Forest Service involvement in rural development comes from the 1990 Farm Bill in Title XXIII, Subtitle G, "Rural Revitalization Through Forestry" (P.L. 101-624). It directs the Forest Service and other Department of Agriculture agencies (Cooperative Extension Service and Natural Resources Conservation Service, among others) to assist rural communities in diversifying their local economic bases. Through coordinated assistance with local institutions, the agencies support "action-oriented," locally developed plans and projects (USDA 1992). For example, the Winema National Forest contributes to diverse projects in communities within the Klamath Basin in south central Oregon. Although contributions tend to be small ($2,000 to $15,000), they often serve as catalysts to initiate projects (Haugen 1994).

The National Forest-Dependent Rural Communities Economic Diversification Act in the 1990 Farm Bill also sought to provide assistance to rural communities located near national forests that fit a specified definition of "economically disadvantaged" due to the loss of jobs or income derived from forestry, the wood products industry, or related commercial enterprises such as recreation and tourism in the national forest" (Ashton 1995).

In examining community economic stability, the distinction between the business needs of industry and community economic needs is often overlooked (Society of American Foresters 1989). Although employing local residents, industry interests inevitably differ somewhat from the communities in which they are located. Both communities and industry are substantially affected by forces beyond their control. The community has little influence on decisions made by the business firms operating in its area, and the firms may have little influence on macroeconomic forces that influence their operations. Because of these factors, rural communities often find themselves vulnerable to boom-and-bust cycles, commodity price fluctuations, and national and regional recessions.

Past agency efforts designed to maintain community stability have centered on providing stable, high flows of commodities, especially timber. However, the Economic Assessment concluded that "the literature is ambiguous at best regarding the relationship of sustained timber yields and community stability, as measured by employment in the timber industry." Many factors undermine the potential use of an even-flow supply of timber to stabilize rural communities regarded as timber dependent. Aside from the macroeconomic forces that are beyond local control, federal managers have been unable to deliver an even flow of timber according to projections because of the need to manage for other uses and meet changing public desires. In addition, Federal timber can be purchased and transported long distances rather than purchased locally and used to provide jobs in the community. Stabilizing an industry is not the same as stabilizing a community.

Contemporary guiding legislation (NFMA and FLPMA) for both the Forest Service and the Bureau of Land Management, respectively, is oriented toward planning methodology rather than specific economic or social policy goals (Dana and Fairfax 1980). However, many citizens believe that the agencies have established a social contract with rural timber communities based on past practices. Observers such as Lee (1994) have suggested that sudden departures from past practices have resulted in feelings of abandonment, violation, and helplessness by people in timber-dependent communities. Such beliefs undoubtedly influence the many current attitudes toward the agencies discussed earlier in this chapter.

Relative to rangelands, holders of Federal range allotments often experience gains in property value stemming from their access to Federal forage (Frewing-Runyon 1995) although grazing permits are not a property right. This expectation reasonably evolved from past relationships and land uses,

yet changes in Federal grazing allotments could result in decreased value of base properties that are not compensable. The intense social and political debate over rangeland reform reflects the difference in beliefs and values regarding management of grazing on Federal lands.

Community Resiliency

Many social scientists documenting the challenges facing rural communities throughout the Nation have recently concluded that stability is just one way to achieve the broader goal of healthy, prosperous, interesting, and vital communities. Just as stability may not be a better goal than growth or diversification, even-flow resource outputs and volumes are not necessarily the best path to healthier communities:

> *Community adaptability may be more useful than community stability in assessing which communities will prosper in a rapidly changing world reflected by such factors as imagination of community leaders, the ability to access information, and the availability of a diverse resource base (Beckley 1995).*

Mindful of the destructive boom-and-bust cycles that accompanied 19th century forestry, the Forest Service argued that the non-declining even-flow policy was necessary to assure community stability. Their analysis assumes, first, that stability is an accepted goal, as opposed to, for example, growth, diversification, or reorientation of a community's economic base; second, that the Forest Service has a mandate and a capacity to contribute to that goal; and third, that even flows of timber volumes from Federal lands contribute to that goal. None of these assumptions is broadly accepted as a working assumption (Dana and Fairfax 1980).

Social scientists have used several terms to describe community health. Flora (1995), Jakes and Harms (1995), and various works in progress by rural development councils throughout the United States have referred to "community vitality" as a measure of community well-being that incorporates generation of wealth; condition of surrounding biophysical resources; economic diversity; strategic preparedness for the future; organizational connection; and the skills, initiative, and confidence of community members.

FEMAT (1993) defined "community capacity" as the ability of community residents and institutions to meet local needs and expectations, based on physical infrastructure, human capital, and civic responsiveness. Some previous definitions of stability were extremely close to those concepts: "Community stability is best defined as a process of orderly change within those political and geographical areas that are significantly affected socially or economically by forest resources...community stability concerns the prosperity, adaptability, and cohesiveness of people living in a common functional geographic area and their ability to absorb and cope with change" (Society of American Foresters 1989).

Harris and others (1996) used the term "community resiliency" to refer to a community's ability to respond and adapt to change. This term is essentially an expansion of the community capacity definition, further defined through primary research conducted specifically to learn more about small, rural communities in the Basin (Harris and others 1996). Using community resiliency in assessment moves the discussion from the previous goal of maintaining timber-dependent communities by supplying an even flow of timber, toward a broader social goal of maintaining healthy communities throughout the Basin, and gives special attention to towns that rely on opportunities provided by public lands managed by the FS and BLM.

This chapter focuses on "community resiliency" as the preferred term. However, resiliency in this context does not equate to the traditional definition of resilience, which is the capability of a body to recover its original shape after deformation. Instead, resiliency as applied to ecosystem management reflects the ability of people to manage personal and community transitions with some degree of comfort and confidence in the face of powerful forces of change. Selection of the term "community resiliency" does not mean that

definitive measurements of many of its components have been obtained, nor that all of the attributes contributing to community resiliency have been measured. These factors make it clear that additional conceptual development is needed to assess these terms and their predictive capabilities.

Components of Community Resiliency

In their literature review of conditions that contribute to community health, Harris and others (1996) identified numerous characteristics that could help determine a community's resiliency: community character, cohesiveness, services, and infrastructure; autonomy; economic diversity; resource dependence; attractiveness to business; quality of life; leadership; effectiveness of community government; and preparedness for the future. Based on this information and the work of other social scientists researching community issues, five factors are identified for closer inspection because of their key links to assessing community resiliency: population size, economic diversity, civic infrastructure, amenities, and location. Although each factor is discussed separately below, additional research of these factors is needed in other settings and for other data to validate the significance and interactive effects of these and other variables relevant to public land management.

Population—Harris and others (1996) identified population size as a global indicator of resiliency; much like the resiliency of many biophysical ecosystem components, community resiliency is affected by scale. Communities having larger populations possess greater amounts, and wider diversity, of human capital than smaller towns and tend to show higher levels of resiliency as a consequence. Larger communities also tend to have higher levels of economic diversity, which cushion job losses in times when industries decline; in other words, their economy does not depend heavily on a single industry or business firm. Also, in a larger economy, less money leaks from the local economy to pay for goods purchased outside the community.

Participants in community self-assessment workshops held in approximately 200 communities throughout the Basin during 1995 (Harris and others 1996) viewed larger towns more positively. Smaller towns tended to be viewed as less attractive, less friendly, and less vital to business. Among the exceptions of these viewpoints were representatives of intermediate-size communities (3,000 to 5,000 population) who viewed their communities as more autonomous and friendly than did representatives from either smaller or larger towns.

It is not likely that land-use decisions of the FS or BLM will substantially affect the resiliency of the communities having larger populations and economies, although certain members of these communities whose occupations are tied to natural resources may be deeply affected.

The converse is generally true for communities with small populations having fewer industries and business firms per economic sector. Even where many industries are represented, each may include only a few businesses. A decline in one industry or loss of a business firm, especially a major employer, can mean high job loss in the community until adjustments are made. This can be especially disruptive if the community is geographically isolated and has limited alternative employment opportunities. This situation describes many rural communities with a high proportion of employment in agriculture and natural resource commodity industries. It is reasonable to expect that land-use decisions of the FS and BLM could affect industries important to communities with smaller populations near lands administered by these agencies, especially in the geographically isolated areas. However, as will be discussed below, resiliency cannot always be predicted from a community's population size.

Economic Diversity—Harris and others (1996) created employment profiles for more than 450 communities in the Basin, which they used to develop indices of economic diversity at the com-

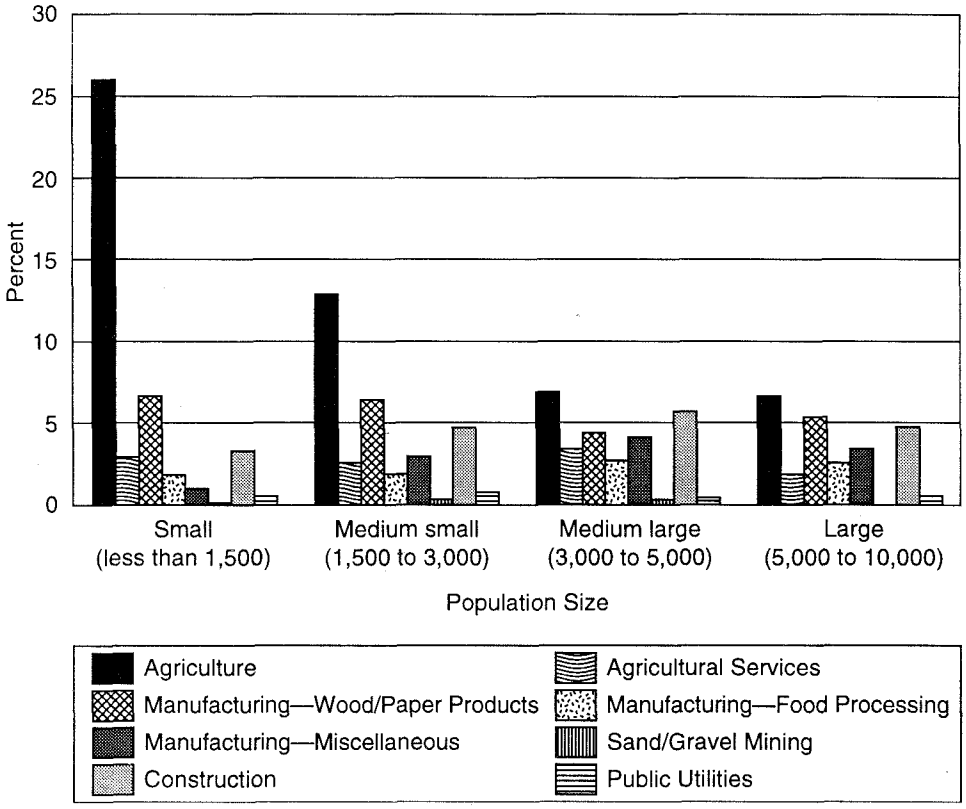

Figure 7.4a - Community employment profiles by size of community. (Note: The scales for figures 7.4a-c are not identical relative to percent of total employment.) (Source: Harris and others 1996).

munity level. The resulting economic diversity values represent a relative index of the employment structure based on the number of industries reported in a town and the proportion of the workforce working in any single industry. The greater the number of industries and the higher the distribution of the workforce across industries, the higher the index value.

Although larger towns tend to have a higher degree of economic diversity than smaller towns, a greater population does not always guarantee a more diverse economic structure (figs. 7.4a-c). Employment comparisons by industrial sector show that many smaller communities are as diverse as larger ones. An exception includes agriculture (farming and ranching), which comprises a larger proportion of employment in the smallest towns (26%) than in the largest ones (7%). Larger towns also contain higher proportions of employment in business, personal, and medical services.

As part of the community self-assessment workshops (Harris and others 1996), participants were asked for perceptions of their community's economy. People perceived farming and agriculture as most important in terms of community dependence on natural resources, followed by grazing and ranching, outdoor recreation and tourism, forest products, and mining and minerals. People perceived that most towns' economies were linked to a mix of natural resources; only 9 percent of the communities were perceived as highly independent of farming and ranching,

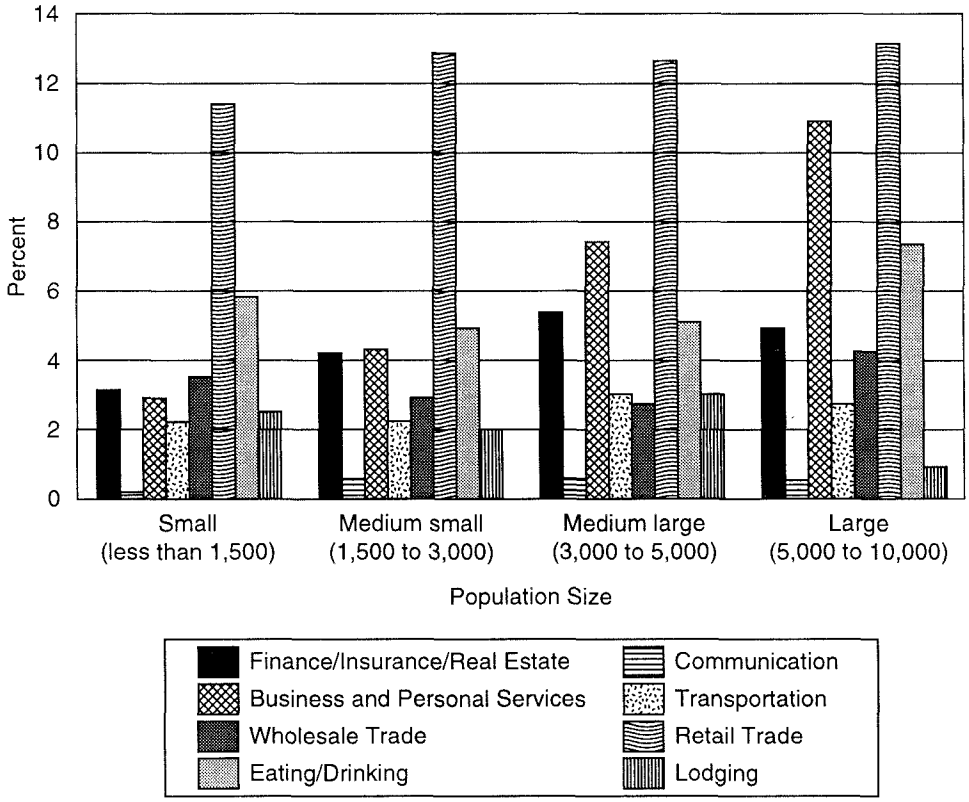

Figure 7.4b - Community employment profiles by size of community. (Note: The scales for figures 7.4a-c are not identical relative to percent of total employment.) (Source: Harris and others 1996).

13 percent independent of tourism and recreation, and 37 percent independent of timber. About 25 percent of all communities were viewed as having a mixed economy, with no particular dominant industry.

These perceptions were compared with the actual economic profiles of each community. Overall, people were fairly accurate in their perceptions, but they tended to underestimate the diversity of their economy and overestimate the importance of traditional industries. For example, 71 of the communities in the Basin were determined to have high employment (10% or greater) in wood products industries; of these, 37 were among the approximately 200 communities studied in detail. People were very accurate in recognizing timber dependence; 92 percent of the participants from these communities said timber was an important component of the economy. However, of the 161 communities studied in detail in which less than 10 percent of employment was in wood products, 37 percent were perceived as highly dependent on timber.

As another example, 321 of the Basin communities were determined to have high employment (10% or greater) in agriculture; of these, 138 were among the approximately 200 communities studied in detail. People were very accurate in recognizing the importance of agriculture; 91 percent of the participants from these communities rated their town as highly dependent on agriculture. However, 58 percent

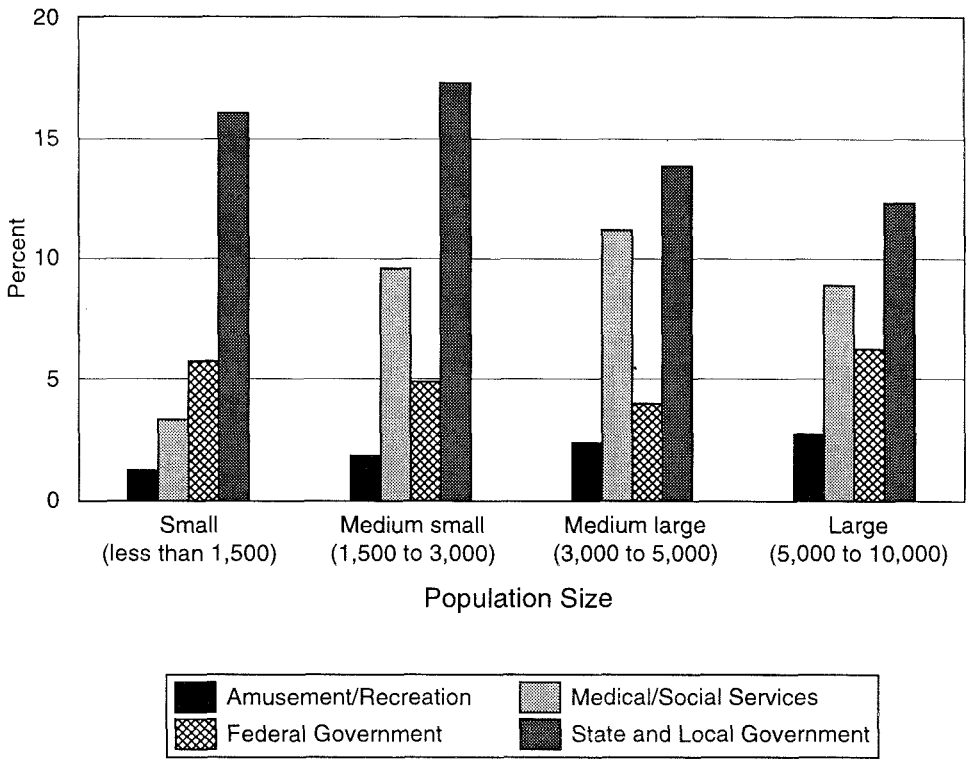

Figure 7.4c - Community employment profiles by size of community. (Note: The scales for figures 7.4a-c are not identical relative to percent of total employment.) (Source: Harris and others 1996).

of the 60 communities that had below 10 percent employment in agriculture were perceived as highly dependent on this industry.

There could be several explanations for these differences between perceptions and the empirically measured economic structures: people could simply be overestimating dependence on timber or agriculture; people could be basing their perceptions on income effects or social influence instead of percent of employment; or the use of 10 percent as a threshold for employment could be inappropriate. Regardless of the explanation, it is clear that the debate over resource dependence in the Basin will continue, and that perceptions may not always match actual conditions.

When considering the significance of wage levels (income) to community members, using economic diversity as a measure of community resiliency may only tell part of the story. Although economic diversity may show greater opportunities in employment options, it does not show the effect of wages on the lives of community residents. Lower-wage jobs in communities may result in greater stress on families; both parents may be forced to work, or one may have to take multiple jobs. These types of pressures, along with an increasing number of single parent households, may negatively affect both community resiliency and quality of life for individuals and families.

Civic Infrastructure—Unlike population size and growth, employment and wages, and economic diversity, the human imagination and energy that contribute to community resiliency are difficult to measure. Human initiative is believed

Table 7.2—Self-assessment of communities' preparation for future.

Category of Response	Number of Communities	Percent
Community has plans and projects identified that will allow them to stay the same.	7	3.5
Community has plans and projects identified that will allow them to change and achieve a desired future.	61	30.8
Community has discussed and identified future directions, but not identified any actions.	78	39.4
Community has had little discussion about the future, and wants to stay the same.	36	18.2
Community has had little discussion about the future, but is willing to change to endure into the future.	16	8.1

to be a significant consideration for community adaptability (Flora 1995). Institutional features of civic responsiveness (such as community leadership, planning operations, and local government effectiveness) and individual characteristics that would support a "civic culture" (levels of education and professional employment) are likely variables to consider.

An objective of the community self-assessment workshops was to identify civic and cultural attributes important to communities. Based on these workshops and assessments of 10 case-study communities that have experienced significant change in the past decade, three elements emerged as important components of the factor called "civic infrastructure":

- Strong civic leadership—A high commitment of individual leaders and groups to community and active involvement in creating and/or responding to change; a strong sense of local control regardless of external events or influences.
- Positive, proactive attitude toward change—Residents either promote change and thus vitality in community development or, if change is occurring on its own, residents respond positively and create a desirable future.
- Strong social cohesion—A high degree of consensus in values and goals for a desired future; working together to achieve goals.

Communities vary across the Basin in their self-evaluations of these three attributes, yet no strong relationships emerge among the above civic infrastructure variables nor any other characteristics of community resiliency. Levels of perceived community leadership, preparedness toward change, and social cohesion appear to be independent of community size, population growth, amenities, or economic diversity.

Preparation for the future varied among communities across the Basin (table 7.2). Although approximately 75 percent of the communities have discussed the future, only about half of those have identified actions for meeting future needs. Of communities that have considered the future, the planned projects are overwhelmingly oriented toward managing themselves toward something new; only a small proportion expressed "staying the same" as a future objective.

These results show that potential may exist for additional dialogue between community members and other potential cooperators about possible actions for addressing changing conditions. The two-thirds of the communities that lack specific plans or projects for addressing change have opportunities to explore alternative strategies and to communicate with other communities about successful projects. The BLM and FS are active participants in many of those efforts, but not in any systematic manner across the Basin.

Individual capabilities of community members may be considered an additional component of civic infrastructure because they may reflect a capacity to contribute toward community plans and projects for the future. Indicators of individual skills, such as education level, could be used as proxies to estimate these capacities. Under the hypothesis that higher levels of education and professional work experience produce a positive effect on community resiliency, data collected at the county level by Force and others (1995) on amount of college education and proportion of the work force in professional occupations were reviewed for any evident patterns. Counties that are urban, contain universities, or have larger towns had generally higher proportions in these educational and skill categories, yet the highest levels of all in Oregon were in the very rural counties of Gilliam and Sherman. In addition, rural counties in western Montana had relatively higher levels of college graduates and professional occupations than other rural counties in the Basin.

The problem with applying these data to communities is that one town in a county with high levels of personal skills may mask the levels in other communities within that county. However, the frequent occurrence of relatively high levels of education in some of the more rural counties indicates that this type of human capability may be well distributed across the Basin.

Amenities—A high degree of physical amenities, such as the historic character and attractiveness of a community's downtown, the attractiveness of the community's setting relative to scenic and recreational opportunities, and the lack of negative elements such as air or water pollution appears to be another important component of resiliency (Harris and others 1996). In general, Basin residents found their communities to be highly attractive. In ratings made during the community self-assessment workshops, the distribution for community attractiveness tended to be on the high (attractive) end of the scale, and there was little overall variation across communities. Although these uniformly high ratings of local perceptions of community attractiveness may reflect the difficulty of community members in providing an objective evaluation of features within or around their communities, scenic integrity of the Basin is generally high as discussed in the section on amenities.

The presence of desirable environmental amenities, and especially the types supplied by public lands, can contribute to an area's population and economic growth. Tourism and recreation, retirement settlement, and other opportunities supported by Federal lands can be significant sources of jobs and income, as well as personal enjoyment (Society of American Foresters 1989). Some evidence to support this relationship is the high population growth occurring in areas of high recreation importance (Johnson and Beale 1994). Recreation counties tend to diversify more rapidly than others, due to Federal land multiple-use policy that provides an environment for attracting both tourists and permanent residents, such as retirees (Ashton 1995).

Location—Communities are embedded in a biophysical setting of climate, physiography, vegetation, and other features, but also are located within the context of a modern transportation and communication infrastructure that supplies variable levels of service, depending on location. Communities in the Basin were sited based on a number of historical factors such as access to river systems, location of mineral resources, placement of military installations, and location of railroad routes. In today's economy, the ability to be connected to other places and markets presents comparative

advantages for some communities. Towns located next to major highways or regionally important airports that carry high volumes of passengers have obvious advantages in attracting visitors and trade. High speed phone lines and access to information services may also contribute to the relative status of a community's attractiveness for new growth.

A community isolated from centers of growth may have lower resiliency due, in part, to having fewer opportunities to keep businesses and services from consolidating for efficiency. Small communities are more deeply affected by these consolidations because they may have only one outlet, or very few, for a particular type of service. Banks, hospitals, schools, state and federal agencies, and other important service institutions are centralizing operations. Due to this centralization, residents of small communities must travel to larger towns to receive services, forcing smaller communities in the Basin to become increasingly reliant on regional centers. Considering these factors, the Economic Assessment used trade regions as an important scale for economic analysis.

Shopping, culture events and entertainment, doctor and medical treatments, employment, and other general services are main reasons that people connect to larger towns outside their own (Bales 1995). The 10 most frequently mentioned centers providing these services within the Basin are: Spokane and Kennewick (Tri-Cities) in Washington; Boise, Idaho Falls, Lewiston, Coeur d'Alene, and Rexburg in Idaho; Missoula, Montana; and Ontario and Bend in Oregon. Medium-size towns such as Grangeville, Idaho, with an approximate population of 3,200, provide a more restricted range of important services to some nearby outlying communities, such as White Bird and Cottonwood with approximate populations of 110 and 850, respectively.

Reliance on other places would seem to make small communities less autonomous and, perhaps, less resilient as a result. However, Harris and others (1996) identified a strong sense of community autonomy as a contributor to community resiliency, so the relationship between isolation and resiliency is not clear. Isolation also requires that people act more independently to meet their needs, and this self-sufficiency may bolster creativity and an internal cohesion that could help a community face adversity.

Measurement of Community Resiliency

In an attempt to establish a broad measure of resiliency that could be compared across Basin communities, Harris and others (1996) developed the community resiliency index (CRI). The index is a single number computed by combining scores on each of four aggregated resiliency factors (economic structure, civic leadership, social organization, and regional amenities) for each community studied in the self-assessment workshop process. Based on available literature and statistical analysis, each factor received a weight before computing the overall resiliency score; civic leadership was weighted the highest, followed by social organization, economic structure, and amenities. Each community was assigned a score based on this composite variable, which was a relative rating of that community's resiliency compared to resiliency of other communities in the Basin. Harris and others (1996) listed Basin communities and their CRI scores, which were combined to form four CRI classes: high, moderately high, moderately low, and low.

The CRI scores demonstrated that there is no one common formula to achieving community resiliency, but that many strategies have proven successful. Yet, some common characteristics emerged; more-resilient communities tended to:

- Be larger.
- Have an economy based on a mix of industries.
- Be autonomous.
- Have a government rated by its residents as responsive to its public's wants.
- Have plans for adapting to change.

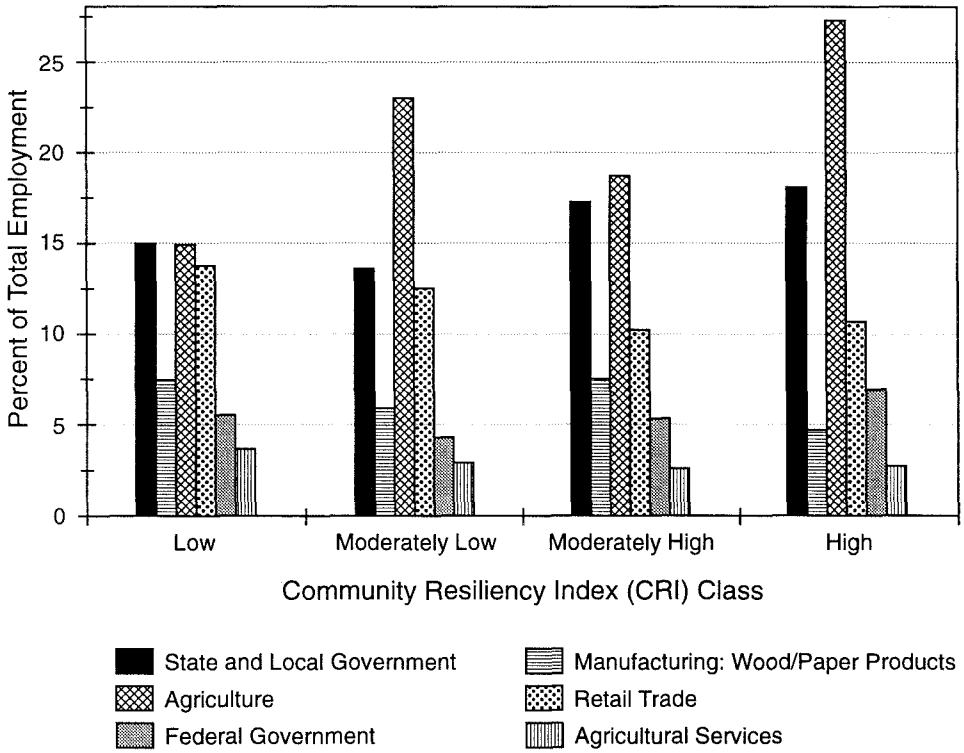

Figure 7.5a - Community employment profiles by resiliency of community. (Note: The scales for figures 7.5a-c are not identical relative to percent of total employment.)

Data relating resiliency class to economic structure suggested few direct relationships (figs. 7.5a-c). Many communities in the most resilient class have high proportions of employment in agriculture, but so do many communities in the moderately low class. Many communities perceived as timber-dominated by community leaders ranked among the highest on the index of community resiliency. Communities confronted with major social and economic changes tended to have higher levels of resiliency. Many on the high resiliency list were communities which had resource processing facilities that had either closed or had production substantially lowered. For example, in Wallace, Idaho a major hardrock mining and processing industry closed in the early 1980s.

The approximately 200 communities studied in detail span all 13 Ecological Reporting Units (ERUs) in the Basin. In general, the Southern Cascades, Upper Clark Fork, and Central Idaho Mountains ERUs had the highest proportion of communities in the high resilience class. Many of the communities with high resilience are in or near mountainous regions that have high amenity values; these communities are responding constructively and proactively to change and, in some cases, are growing in population. The Blue Mountains, Lower Clark Fork, and Upper Snake ERUs had the next highest proportion of communities in the high resilience class; these ERUs also had amenity resources and increasingly diversified economies (Harris and others 1996). The Columbia

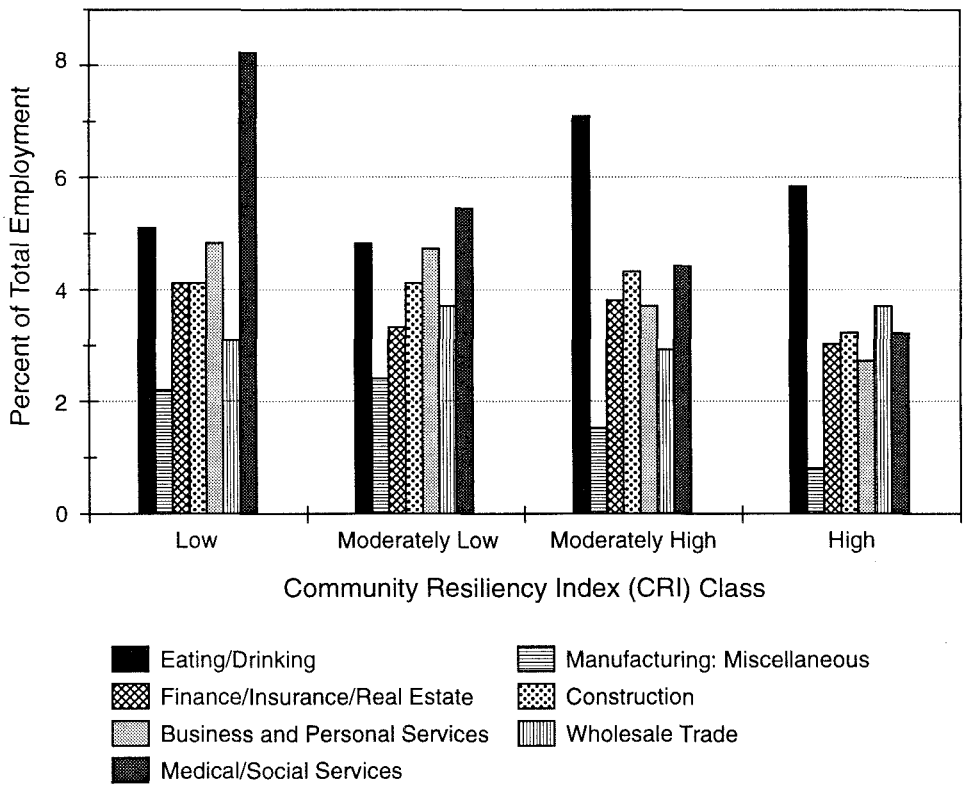

Figure 7.5b - Community employment profiles by resiliency of community. (Note: The scales for figures 7.5a-c are not identical relative to percent of total employment.)

Plateau, Snake Headwaters, and Owyhee Uplands ERUs contained higher proportions of communities in the low resilience class; these were farming and ranching communities perceived as having comparatively fewer amenities. In the Northern Glaciated Mountains, Upper Klamath, Northern Great Basin, and Northern Cascades ERUs, there was either no particular trend in resilience or the number of communities was too small to characterize.

Although the CRI showed the relative resiliency of Basin communities, the index masked the many different ways communities can become resilient. It would be useful to be able to group communities, based on the individual scales used in defining resiliency, for the purpose of identifying different paths to achieving resiliency and of making implications for adapting to change. As a preliminary start in this effort, ICBEMP staff conducted a series of cluster analyses that grouped communities based on similar patterns of resiliency (SPSS Inc. 1989).

The results of the cluster analyses suggested it is useful to think of three types or groups of communities with respect to resiliency. The first group had the highest scores on all five factors comprising the resiliency index; these were communities viewed by their leaders as attractive, economically diverse, and socially cohesive, with strong civic leadership. These communities also tended to have larger populations and exhibited the greatest

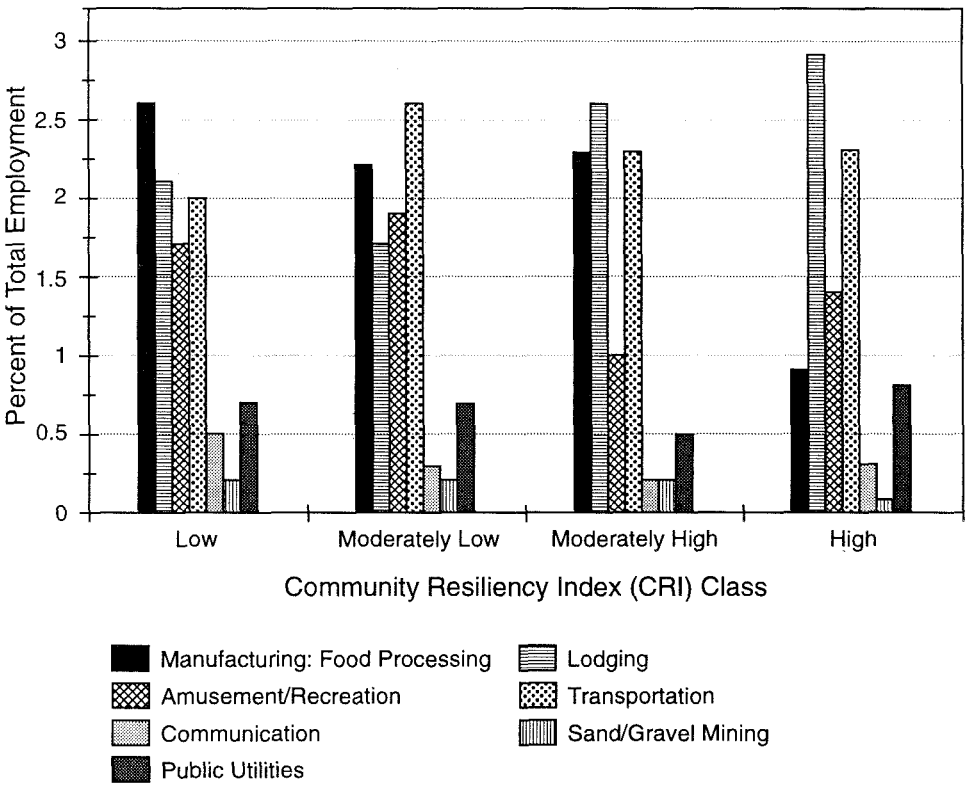

Figure 7.5c - Community employment profiles by resiliency of community. (Note: The scales for figures 7.5a-c are not identical relative to percent of total employment.)

economic diversity. This group tended to contain a larger number of communities than the other two groups. These communities presumably had several different characteristics that would allow them to meet new challenges successfully.

The second group of communities had comparably high scores on civic leadership and amenity values, but much lower scores on social cohesion and economic diversity. Towns in this group were considerably less populated than those in the first group. The number of towns in this group was slightly lower than the number in the first group. Although this type of community may lack the economic base to adapt to change successfully, this shortcoming could be compensated by progressive-thinking civic leaders and the presence of amenities.

The third community type identified tended to have the lowest scores on all measures, although amenity scores were only slightly lower. Intermediate in population, these communities were closer in size to the smallest rather than the largest towns. These communities may have difficulties coping with change because they have few current strengths on which to build. From a Basinwide perspective, this group was by far the smallest, containing just a handful of communities.

Quality of Life

A concept closely related to resiliency and of long-term interest to sociologists is quality of life. Machlis and others (1994) identified numerous indicators of social conditions regularly monitored by various agencies that provide indirect measures of quality of life. Usually collected at the county level, these indicators include conditions such as crime rates, income and employment levels, pollution, and voting rates. Only employment and income can be linked closely to uses of land administered by the FS and BLM.

Because quality of life is subjective, people's perceptions are critical. Relevant perceptions include the attractiveness and aesthetics of the local environment (Pulver 1989) and the quality of services such as infrastructure, medical care, education, and commercial services (Rojek and others 1975). Many of these characteristics could be summarized in the Basin as "small town values." Many local residents who participated in the Interior Columbia Basin Ecosystem Management Project suggested that other factors were meaningless if people did not have jobs.

One measure of baseline conditions for quality of life in rural communities was provided by participants in the community self-assessment workshops (Harris and others 1996). These community leaders and residents generally rated the quality of life in the Basin as high; 80 percent believed their community was "safe, friendly, and a good place to live; few rural communities can match its quality of life." These data also suggested that factors predicting the quality of life include how interesting a community is perceived to be, the level of social problems, community safety, social cohesion, and the attractiveness of the surrounding region. Community population size, however, was not related to perceptions about the quality of life; this perception suggests that increases in a town's size may not, positively or negatively, affect its quality of life (Harris and others 1996).

FS and BLM Roles in Promoting Community Resiliency

The FS and BLM affect the health and resiliency of small, rural communities in the Basin in four main ways:

- Provision of opportunities for *employment and income* through the management of commodities, rangelands, and recreation opportunities, and support for related lifestyles.
- Support of community *attractiveness* through the provision of high quality scenery, healthy forests, clean air, wildlife, and clean water.
- Support of infrastructure and community institutions through *revenue sharing* from the extraction of commodities.
- Support of skills and human capabilities by the *placement of federal employees* in community settings.

The following text on promoting community resiliency focuses on three of these factors (employment and income, Federal revenue sharing, and federal employees); attractiveness is included in the social amenities discussion later in this chapter.

Employment and Income

The Economic Assessment chapter describes employment and income in the Basin and the current roles of the FS and BLM in providing economic opportunities for Basin residents. Its discussion of communities focuses on timber dependency:

> *The Forest Service has implemented specific policy only with respect to timber...Although there is a general sense that the Federal agencies have responsibility toward local economies where they manage a lot of land, not much is known about range dependence...The lessons from the discussion here can be applied to BLM and range-dependence by inference, and other types of resource dependency as well.*

Timber dependency is an issue deeply entrenched in the conventional wisdom of Federal land-use in the West and frequently mentioned by members of the public when addressing agency planning. The issue of community dependency on rangelands generally has not received the same attention as timber dependency. Research on natural resource-dependent communities has focused on timber because of its greater perception of economic value compared to other resources and the resulting social and political concerns. This focus may be changing, as research is beginning to explore effects of amenity management and other nontimber resources on local communities (see later discussion on amenities in this chapter).

There has been much debate about the definition and meaning of timber dependency. Definitions of timber dependency generally stem from two factors: (1) size of the community, and (2) percent of employment associated with timber harvest and processing. In 1977, the Forest Service identified 57 communities in Idaho, Montana, Washington, and Oregon thought to be dependent on National Forest timber, as required by the NFMA. The list, updated and revised in 1987, identified 66 communities in the four states thought to depend on National Forest timber, but also acknowledged there was not a widely accepted definition of "timber dependency." Towns were identified as timber dependent if greater than 10 percent of their workforce was in timber processing and at least 50 percent of their mill supply was from National Forest lands. A community could be labeled timber dependent under current criteria with only a small percentage of employment associated with Federal timber; some have argued that supply must account for much more than this before the production can claim a meaningful impact on an area (Boyd 1989).

The Economic Assessment chapter revisits the timber-dependent list, eliminating communities within 50 miles of one or more towns of at least 10,000 in population and communities in recreation counties. The result was a list of 23 communities deemed to be worthy of attention when developing Federal land-use plans because they are isolated and located in slower-growing parts of the Basin, in addition to being timber dependent.

Burchfield (1995) also re-examined the concept of timber-dependent communities to assess changes since the release of the 1987 Forest Service report. He modified the list by adding communities that Harris and others (1996) found to have more than 10 percent employment in timber processing, as well as 89 communities identified as having timber mills during the data collection for the ICBEMP economic research effort. He also reported other relevant factors of the communities' relationship to Federal lands and timber processing, such as nearby major recreation attractions and average stumpage values. Some communities that appeared on the 1987 list, such as Boise, Idaho, or Missoula, Montana, do not fit today's profile of timber-dependent communities, as both are rapidly growing urban areas with diverse economic bases. Other communities showed changes in their relationship to timber processing by virtue of mill closures or other emerging economic opportunities.

Burchfield's analysis revealed that some communities maintained a high proportion of their workforce in timber processing, and that their locations in close proximity to Forest Service lands argued for closer inspection of the significance of Federal flows of timber in each specific case. Burchfield concluded that several communities (18 in Oregon, 8 in Washington) have greater than 10 percent employment in timber processing. Idaho's Clearwater Valley is another concentration of towns relying on timber. Several of these communities also had populations less than 1,000, possibly suggesting lower resiliency. Both sets of these additional criteria are certain to enter into the debate about timber dependency and the broader issue of links between communities and public land management.

Timber dependency is a social issue as well as an economic one that has many implications for community resiliency. For example, Cook (1995)

examined relationships between poverty and timber dependency in western Washington between 1980 and 1990. She concluded that, "Restructuring of the timber industry during the 1980s coincided with a substantial decline in several indicators of well-being in timber-dependent areas in western Washington, even before the northern spotted owl was listed as an endangered species." She found that poverty in timber-dependent areas rose dramatically compared to rates in nontimber-dependent areas (aside from metropolitan areas). In timber-dependent areas, wage and salary incomes not only continued their importance as a component of household income (in contrast to nontimber-dependent areas, where it declined), but failed to keep pace with inflation. Poverty rates also increased among families with females as heads-of-the-households.

The social effects of economic hardship in natural resource-dependent communities are not unique to timber issues; similar challenges face communities that serve as offshore oil and commercial fishing ports (Freudenburg and Gramling 1994). This finding led those authors to "ask whether natural and human resource preservation and conservation represent a more realistic path to rural community well-being than traditional natural resource extraction activities as we approach the 21st century" (Humphrey 1995).

Regardless of a person's views on the issue, timber harvest today is an important component of economic diversity in some Basin communities. Further reductions in harvest independent of cause would likely lead to negative social consequences that, for some communities, may be difficult to overcome. One reason for this difficulty is that economic opportunities resulting from natural resources on public lands are not just an economic issue, but a social issue that involves chosen lifestyles for many Basin residents:

People bought homes, invested capital, and formed attachments to town communities on the basis of the government's promise of sustained yield in wood production. People in timber dependent communities trusted the government to maintain its commitment to providing continuous wood supplies. A sudden departure from anticipated harvest schedules will force the government to break this trust. Investments in jobs, homes, and attachments to places will be disrupted. Since people have been dependent on the parental good will of their government, they will experience a sense of abandonment, violation, and helplessness that will contribute to the already heavy burden of stress (Lee 1994).

The lifestyles of many Basin residents are linked to their natural-resource-based occupations. People who work in the woods, on rangelands, or on the Basin's many mountains and rivers develop special attachments to the land that can extend across generations. Communities of interest typically develop among people who share a natural-resource-based livelihood and lifestyle. Studies by Carroll (1984) and Carroll and Lee (1990) found that members of occupational communities spend much of their free time with others in the occupation, and look to each other as a primary reference group. While this type of socialization occurs in many groups, the authors believe that occupational communities tend to develop distinctive values and world views centering specifically around their occupation and its culture.

The communities of interest mentioned in this social assessment are a special concern for three reasons:

- They are likely to be impacted by changes in Federal policy, such as ecosystem management, which focuses on achieving desired physical and biological conditions rather than target levels of outputs such as timber harvest.
- The individual identity and lifestyle of these communities are often linked directly to occupations.
- Employment already is shifting downward in many of these industries (logging, mining, ranching, and farming) due to external economic or other factors (Krannich and others 1994), so any additional restrictions could have strong local impacts.

Hovee (1995) described lifestyle characteristics of five natural-resource-related, occupational communities of interest: miners, ranchers, farmers, loggers, and commercial anglers. While each of these occupational interests has somewhat different values, Hovee listed several shared orientations such as hard work, independence, conservative political viewpoints, a utilitarian view of natural resources, and an orientation toward hunting and fishing as forms of outdoor recreation. These occupations tend to be male-dominated, although women are greater participants in operating farms and ranches.

Loggers and ranchers who have a strong lifestyle affiliation with their occupations may be particularly affected by ecosystem management strategies. Hovee (1995) indicated that loggers' values include the following: trees are a renewable resource and are to be harvested as any other agricultural crop; the beauty of the environment and the sustainability of the resource is important; the government is often an impediment to free enterprise and personal freedom; and independence, self-reliance, hard work, and hard play are a sign of good character.

Hovee reported similar values for ranchers: ranchers are caretakers of the environment; stewardship involved in ranching enhances rather than detracts from the environment; ranchers have a sense of intimacy and attachment to the land that "outsiders" cannot achieve; ranchers have an appreciation for peace, quiet, and remoteness coupled with a concern about population growth and encroachment on the resource base; predators present a threat to livestock; and the land defines one's home, identity, and lifestyle. While not all people employed in these occupations share this particular set of values, such descriptions do provide insight into communities of interest.

Carroll and Lee (1990) stated that "identity and shared meanings are key factors in the logger's ability or inability to adjust successfully to dramatic shifts in the demand for labor." This statement suggests that the question of resiliency for communities of interest is also a valid issue. Blatner and others (in press) stated that such occupational communities feel "disenfranchised" in environmental issues, which possibly makes them less able to adapt to policies and leads to unemployment. Therefore, understanding how Federal land-use policies affect communities as a whole is only part of the picture.

Federal Revenue Sharing

County governments provide many community services in rural areas. Local school districts, which operate as independent units of government in each of the Basin states, are institutional fixtures within communities. The schools they administer not only provide education, but offer highly important focal points for community cohesion, supplying community educational needs as well as cultural and athletic events that draw the community together. The condition of schools and roads is a key element that contributes to the quality of life in small, rural communities.

County governments and school districts in the Basin receive Federal revenue sharing payments based on the amount of Federal land in the county and the value of commodities extracted in a given year. Federal revenue sharing in the Basin occurs under the Mineral Lands Leasing Act of 1920, the Taylor Grazing Act of 1934, the Twenty-Five Percent Fund, and Payments in Lieu of Taxes (PILT), with the latter two being most important to county governments and school districts.

Under the Twenty-Five Percent Fund, 25 percent of the revenues from sales of Federal commodities are returned to the states, with stipulations that it be expended for roads and schools. The states decide the proportional distribution to each; Montana and Idaho each give about two-thirds to roads and one-third to schools (Schuster 1995a). PILT payments are revenues returned to counties as compensation for tax-exempt Federal lands (Shuster 1995b); these monies are distributed to counties based on a payment formula that includes consideration of the amount of Federal land within the county boundaries and county population levels.

A major incentive for local government officials to support timber harvest on national forests is the linkage between the value of timber harvested (based on price and volume) and the amount returned to counties (for roads) and school districts under the Twenty-Five Percent Fund. The higher the harvest value, the greater the local share. The Economic Assessment chapter describes many other factors that influence Federal payments and also points out that recreation, which generates greater economic value than other land uses, does not contribute to revenue sharing payments because recreational opportunities on Federal lands generate little Federal revenue.

Schmit (1995) found that nearly one-third of Basin counties receive additional benefits due to added revenues from the Twenty-Five Percent Fund; the majority of counties receive baseline PILT payments of $0.75 per acre regardless of harvest revenue (table 7.3). The largest per acre benefits accrue to counties on the far western edge of the Basin that have moist forest environments with high timber volumes per acre.

Important benefits also accrue to counties such as Grant County, Oregon; Lincoln County, Montana; Shoshone County, Idaho; and several others with small communities that are losing population and have a high percentage of the workforce in timber processing. In these communities, Federal timber harvest could be important to community resiliency for the support given to community institutions such as schools or civic projects, as well as the direct employment benefits. Recent decreases in Federal timber harvest levels have led to 50 percent cuts in revenue-sharing payments in eastside counties. Even in counties where the per acre benefits of the Twenty-Five Percent Fund payments are only slightly higher than the PILT baseline, there may be a large amount of Federal land that presents a significant increment of revenue.

As mentioned above, the value of payments to counties from the Twenty-Five Percent Fund is also greatly affected by the price of timber. Between 1987 and 1994, when the price of timber increased by 75 percent on the Basin's national forests and harvests dropped by 64 percent, the higher price of timber sustained the value of revenue sharing payments at near constant levels (Schmit 1995).

Federal Employees

Another way the FS and BLM affect communities is placement of staff in rural areas to implement management activities. Data collected by the ICBEMP in 1995 show that the Forest Service had just over 8,000 field employees (approx. 63% permanent and 37% temporary) and the BLM 900 field employees (approx. 82% permanent and 28% temporary) in the Basin, with most located in smaller communities. In some of these communities, one or more agency offices can comprise a significant portion of the local economy.

The diverse backgrounds and disciplinary specialties of FS and BLM personnel offer communities highly valued skills for planning, engineering, design, communications, and other skills that have value in small, rural communities (Rodriguez 1995). The contributions of FS and BLM staff in rural areas demonstrate a solidarity with communities and the rural environment that is not well demonstrated by the behaviors of professionals in other occupations. As Lasch (1995) observes, there is a general trend for well-trained "elites" to abandon small towns and the traditional "middle class culture" for the allure of urban centers and fast-paced lifestyles, leaving few skilled "symbolic analysts" to remain in rural areas and small towns to assume the tasks of a technologically dependent society.

Table 7.3—Counties receiving extra benefits from timber harvest (1992).

County	Payment per Entitlement Acre (In dollars)	Total Payment (Prior year + PILT) (In dollars)
Wasco, Oregon	$9.37	$1,954,157
Hood River, Oregon	9.21	1,931,000
Skamania, Washington	6.30	5,240,749
Klamath, Oregon	4.77	10,227,422

Implications for Ecosystem Management

The current pace and nature of changes in the Basin suggest that the manner in which the FS and BLM interact with communities be carefully reviewed. Old behavior patterns that characterized land management priorities may no longer serve the interests of many community residents. Policies to promote community stability may be inappropriate under conditions where there is little stability in the social system.

Many communities have long-standing social, cultural, and economic ties to FS- and BLM-administered lands in the Basin. Numerous Federal laws, regulations, and policies refer to this relationship, but few systematic attempts have been made to inventory the meanings of important places on public lands. Conducting place assessments at the community level would be one way to address this important ecosystem feature, as well as to begin meaningful community involvement. Public interactions with Federal managers, planners, and lawmakers at every level of government clearly show concern for Federal land uses and communities, and is an issue often cast as community "dependency" on Federal lands. Presenting the relationship of Federal lands and communities as "dependency" connotes an image of powerlessness among those dependent communities, and yet, as demonstrated by the discussion on community resiliency, communities have considerable capacity through their civic infrastructure and other factors to direct their own futures.

Traditional descriptions of dependency focus most attention on the provision of employment based on timber production. Others (Haynes and Horne, chapter 6; Rasker 1995) have shown that recreation supplies higher levels of employment than timber management in the Basin, and other social factors (macroeconomic relationships, growth, and family structure) have greater effects on the well-being of rural communities in the Northwest than does timber production (Heberlein 1994). Even though it is difficult to predict any direct effects that timber harvests in a given National Forest may have on a given community, inferences can be made about geographically clustered communities in areas having high proportions of Federal land. Lower levels of timber harvests on National Forests in these areas may diminish the resiliency of these communities by reducing the number of timber-related jobs and income that support individual families, community businesses, and civic infrastructure. The wood products industry contributes to economic diversity in communities across all Basin states.

Notable among the groups of communities in the Basin that appear to be most vulnerable to change are:

- Clearwater Valley in Idaho, where communities are already experiencing population decline and reduced timber harvests from FS-administered lands (Harris and others 1996).
- Isolated communities in western Montana that are outside the growth hubs of Kalispell and Missoula.
- Isolated, small communities in eastern Oregon that are not receiving the growth of the region's medium-sized towns.

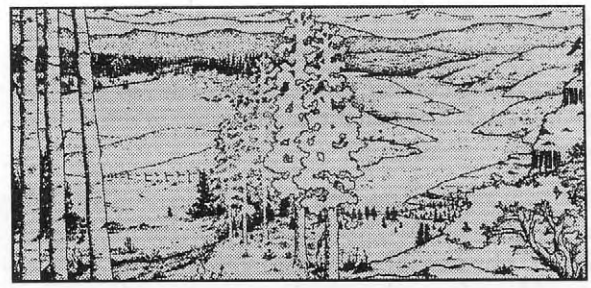
The relationships of these towns to Federal resources could be more closely examined at the Forest Plan decision-making level. This level can give a better understanding of the opportunities to mitigate potentially negative consequences of further reductions in timber harvests from national forest lands. Economic analyses are important not just at the regional scale, but at county and community scales as well. Each level of analysis has its own most appropriate uses, with a different story at each scale because each is a crucial part of the ecosystem. Issues and concerns emerge at one scale that may not be present at another. In addition, agencies could develop a better understudy of how resource management decisions affect employment in other industries.

Although the resiliency concept is useful, it deserves additional attention to be fully developed. As stated above, there are many ways in which a community may be resilient. A community may have small population size but strong civic leadership, therefore having the ability to maintain itself through creative solutions to problems. A highly cohesive community may be able to overcome limited economic diversity by cooperating together to attempt new business endeavors. Even though a community may be resilient, its interests should be considered in ecosystem management.

Measuring community resiliency presents problems for researchers, because it involves complex interactions between personal skills and institutional behaviors. The CRI must be viewed as provisional; humans and the communities they inhabit have proven through history to be remarkably adaptable, and the multiple, interacting factors that affect this adaptability make prediction highly uncertain. If people's ties to their communities are strong enough, they often make surprising sacrifices (commuting hundreds of miles for employment or accepting lower pay, for example) to continue to reside in their homes. Adversity often motivates people to be resourceful, and as Harris and others (1996) observed, Basin communities that have undergone some of the most severe shocks have successfully restructured their economic and social relationships. Therefore, attempts to classify communities based on resiliency must be viewed with considerable restraint, as the procedure itself may have negative consequences for communities that are rated as less resilient or healthy than others (FEMAT 1993). For this reason, this social assessment does not describe individual communities and their resiliency.

Social impact assessment can consider resiliency as both an independent variable that determines how communities will respond to effects and as a dependent variable that can be affected by Federal and other policies and projects. The community self-assessments have been a valuable information source about communities for this social assessment, as well as for the Draft EISs. This process was welcome in nearly all communities. Although participation was limited to a few people from each town, the process served as a starting point for a new interaction approach with communities. While many FS and BLM employees who live in the Basin's small, rural areas participate in community affairs in various capacities, these relationships could be formalized and structured to meet mutually desirable objectives for the relationships between public lands and communities.

The outcome of the old-growth controversy west of the Cascades provided a recent precedent when the Federal Government helped ameliorate the impacts to timber workers whose jobs were lost by the need to protect habitat for the spotted owl. "Jobs in the Woods" and other specialized transition programs were authorized over a three-state area, and a special White House Office on Forestry and Economic Development was established in Portland, Oregon, to oversee Federal, State, and local efforts to support people and communities in the affected area. The high visibility of this federal response elevated expectations that the Federal Government would act to buffer changes caused by reductions in flows of commodity product from FS- and BLM-administered lands even though the overall impacts on job losses in the region have been less than anticipated (Sleeth 1995).



Although efforts by agencies to support economic diversity may also be important, the demands of the marketplace and the operation of the economy on a larger scale may make attempts at increasing resiliency more difficult. Economists, as well as members of the public, differ with respect to the acceptability of agency activities such as sustained yield units, special provisions for certain contractors, and other attempts to manipulate the market to achieve social and economic objectives. Monitoring these efforts to assess their long-term social, economic, and environmental effects will help to identify characteristics of the most useful approaches.

SOCIAL BENEFITS OF AMENITIES ON PUBLIC LAND

The environmental amenities of the Basin are significant components of not only the region's identity (Angus-Reid 1993), but the quality of life for current and future residents. The principal motivation and source of satisfaction for many visitors are the extensive wildland-based sceneries that typify the Basin (Christensen and others 1995). The environmental amenities that tourists find attractive are also appealing to the region's residents, and are reasons that people either remain in, or migrate to, the Basin.

The term "amenities" has been used in many ways. In the context of ecosystem management, "amenities" refers to environmental aesthetics and opportunities to appreciate them. This includes scenery and associated opportunities to recreate in natural-resource-based settings in areas both with and without roads. In the past, the use of amenity resources has been called "nonconsumptive" compared to timber harvest, grazing, and mining, which were typically viewed as "consumptive." However, all land uses are consumptive in a social sense; using land in one way may make it less available for other uses and may also emphasize the importance of some ecosystem conditions and processes over others.

By emphasizing restoration of ecosystem health and functioning, ecosystem management may lead to changes in landscape conditions that could enhance some forms of recreation but limit or alter others. For example, it is reasonable to expect increased concern about the effects of roads, particularly in sensitive areas such as riparian systems. This issue is complex because roads provide recreational access essential for some types of activities and experiences, but can detract from others. Some restoration treatments, such as thinning and prescribed fire, can be expected to have mixed effects as well, both on recreation opportunities and scenic quality. It is therefore important to have an overview of amenity resources in the Basin, both to better understand this component of the ecosystem and to serve as a baseline for measuring change.

This discussion on social benefits of amenities describes the principal amenities and sites in the region, with an emphasis on recreation opportunities and scenery measured at the broad scale. Some information is summarized from the Economic Assessment (chapter 6), which contains a complete discussion of recreational opportunities. The discussion on amenities concludes with implications for ecosystem management and recommendations for future assessments at finer scales.

Recreation Opportunities

Recreational opportunities contribute significantly to the quality of life for Basin residents, as well as people who visit the Basin. Lee and Driver (1992) identified four major types of benefits derived from recreation participation:

personal, social and community, economic, and environmental. As discussed in the Economic Assessment (chapter 6), recreation settings on public lands also benefit people who do not actually visit the sites.

Recreation, tourism, and related industries are among the fastest-growing economic sectors in the Basin. The Economic Assessment (Chapter 6) provides information on the economic values associated with Basin recreation opportunities, estimated annually at $1.2 billion. More than 80 percent of this value stems from opportunities on lands administered by the FS or BLM. Recreation also supports at least 200,000 jobs Basinwide.

The Basin provides a diversity of outstanding, nationally known recreation settings. Many of the most important opportunities that are based on natural resources are located on lands administered by the FS or BLM. These existing local, regional, and national resources can be affected in many ways. For example, population growth increases not only the demand for ecosystem goods and services, but also the land and resource requirements. Such growth also affects the environment directly through conversion of vegetation and open space to residential, commercial, industrial, and transportation uses.

Supply of Recreation Opportunities

Counties in the Basin have, on the average, substantially greater amounts of available recreation resources compared to the national average. Aside from the central Rocky Mountains and the Colorado Plateau, the Basin is among the richest regions in the Nation for environmentally based amenities. The Yellowstone Ecosystem on the Basin's eastern edge, the birthplace of the national park system, contains an ecologically outstanding and economically important set of amenity resources. To the northeast lies the area surrounding Glacier National Park, a spectacular demonstration of geology, vegetation, and ecological processes. Both areas show the need for ecosystem-based strategies that cross agency boundaries.

The northwest portion of the Basin contains equally well-known mountains, forests, rivers, and wildlife in the northern Cascades. The southwest portion of the Basin contains Crater Lake National Park and the Klamath Basin, a vegetatively complex region of natural resources.

Near the Basin's center are the Frank Church River-of-No-Return and Selway-Bitterroot Wilderness Areas, both uncommonly large unroaded areas that retain some of the Nation's most significant wildlife populations. Hells Canyon, located on the Idaho-Oregon and Idaho-Washington boundaries, is one of the deepest canyons in North America. It provides outstanding whitewater recreation opportunities, as do the Snake River in Wyoming, the Salmon and Selway River systems in Idaho, the Deschutes in Oregon, and many other Basin rivers.

On a comparative basis, the Basin has abundant amounts of protected areas, which equate to about four acres of Wilderness Areas, National Parks, or National Recreation Areas per person; this ratio is nearly seven times the national average. The project area contains 70 percent of the unroaded areas that are 200,000 acres or larger in the lower 48 states. These areas provide not only important habitat for wildlife, but singularly distinctive opportunities for people to experience primitive recreation. The combination of large-scale protected areas and low population density provides much of the regional identity.

The Recreation Opportunity Spectrum (ROS) inventory described in the Economic Assessment (Chapter 6) found that about 60 percent of Federal lands in the Basin provide roaded natural opportunities, 40 percent are considered primitive and semi-primitive, and less than 1 percent are rural. A large amount of the supply of the semi-primitive class is not currently in a protected status. Semi-primitive opportunities are the most scarce and also those most at risk in terms of potential changes due to development, especially of roads.

The ROS is a convenient way to inventory and display recreation settings based on access, level and type of development, and other social and managerial characteristics. ROS does not, however, consider the main attractions that draw people to recreation settings, such as specific recreational facilities, water, fish, and wildlife. Many destination ski areas located on FS-administered land are part of a package of amenity resources that create tremendous attraction among both residents and nonresidents.

The presence of water has been, and will continue to be, the most important attractor for recreation visitors. Among recreational resources, free-flowing rivers stand out as "a nonrenewable and rapidly disappearing feature of the American landscape" (National Academy of Sciences 1979). One resource advantage for the Basin over the surrounding area is wild and remote water environments; the average for Basin counties is nearly three times the national average, and more than double the average of adjacent counties. The Basin contains some of the Nation's best fishing and whitewater streams. The River Information Digest (American River Management Society 1992) identified whitewater river segments that were at least 10 miles in length or that were designated as components of Federal-, State-, or local-protected river programs as small subsamples of unique recreational river segments in the Basin. The digest described 46 outstanding rivers for recreation in Idaho, 15 in Montana, 29 in Oregon, and 19 in Washington.

In the future, the Basin is expected to continue to have substantially more available recreation resources than the Nation as a whole. For most recreation environments, the resource base for the western United States is expected to grow more rapidly, or decline more slowly, than the eastern portion of the country (English and others 1993). Similarly, the Basin should continue to have greater availability of most recreation resources than surrounding areas.

Demand for Recreation Opportunities

As described in the Economic Assessment, between 1991 and 1993, about 200 million recreation activity days per year occurred on federally administered public lands in the Basin. Roaded natural settings received about 75 percent of all activity days. Activities most frequently measured by activity day include day use and motor viewing, camping, fishing, trail use, and hunting.

Just more than six million people were estimated to have participated in wildlife-oriented activities within the four main Basin states. Wildlife viewing, photography, and related wildlife activities were more popular than hunting and fishing in all four states. Many of these visits were made by people residing outside the Basin. For example, 22 percent (1.4 million) of Basin visitors who engaged in wildlife-oriented activities were nonresidents of the four major states comprising the Basin.

A significant portion of the overall nonresident visitation originated from the nearby metropolitan areas of Seattle, Portland, and Salt Lake City. The Basin also is an international destination; more than three million Canadians visited the Basin's four main states. International visitations to the Basin from countries other than Canada totaled about 123,000 visits, and most of these visitors were from western Europe or Japan. Projected international visitation in the Basin's four main states for the year 2000 is almost seven million visitors.

As noted in the Economic Assessment, the following social and economic characteristics of the United States population influence participation trends:

- An aging population with older-aged individuals having much leisure time.
- Increasing population levels.
- Increasing ethnic diversity, resulting in a greater variety of recreational demands.
- Population migration, from urban areas to more rural areas.
- A narrowing of the middle class.

All of these characteristics greatly influence the types of activities in which individuals participate, the length and season of recreation participation, and the frequency of participation.

Although lack of consistent data among land management agencies prevents calculating an annual percent change in participation levels for the entire Basin, recreation participation has been steadily increasing over the past 15 years. The BLM indicated a slight decrease in participation in 1995, but otherwise had been experiencing a steady increase in visitation the last 10 years. Nationwide, the five fastest-growing outdoor activities between 1982 and 1995 included birdwatching, hiking, backpacking, downhill skiing, and primitive camping (Cordell and others 1995). Projections made by the states of Oregon, Washington, Idaho, and Montana in their Statewide Comprehensive Outdoor Recreation Plans showed that trail use, a majority of which takes place in less developed settings, is expected to be one of the fastest-growing activities in all four states.

Nationally, the greatest shortages in recreational opportunities are expected to be for primitive camping, backpacking, hiking, horseback riding, nature study, and wildlife observation (Cordell and others 1990). The Economic Assessment described this national shortage as a comparative advantage for the Basin and one that will increase in value. Within the Basin, demand for developed camping, family gatherings, visiting museums, bicycling, running and jogging, and outdoor-pool swimming is anticipated to increase at least 250 percent in the next 50 years (Cordell and others 1992). Although all activities are expected to increase in participation, gathering firewood and collecting berries are expected to have relatively small increases in demand.

Scenery

Scenery, the general appearance of a place and the arrangement of its individual features, is another type of Basin amenity. Scenery consists of both *biophysical* and *cultural* elements. Biophysical elements include land forms, water, and vegetation; cultural elements include buildings, rock walls, and fences. Scenery is the product of both natural processes and human culture, combined in varying proportions (Eckbo 1969). Therefore, it is a resource vulnerable to change because virtually everything humans do in terms of management activities has an effect on the appearance of an area.

Human intervention in natural processes has been a major force in shaping landscapes within the Basin. Of the Basin's more than 144 million acres, over 37 million acres (26%) have been transformed by the agricultural and industrial undertakings of humans to the degree that their overall images are no longer near-natural in appearance but are culturally dominated.

Landscape appearance and scenery are important environmentally based amenities, not just as settings for recreation, but as components of the Basin's image to residents and nonresidents. Basin residents consider the scenic quality of Federally managed lands to be important. FS- and BLM-administered lands often serve as backdrops for communities and residences in both rural and urban settings scattered throughout the Basin, offering a large area of wildland-viewing opportunities. These same lands also provide settings for a variety of occupational and recreational activities serving a wide diversity of people living both inside and outside the Basin.

Attempts to define and measure public perceptions of scenery and aesthetic values began in the 1960s, gained momentum in the 1970s (Elsner and Smardon 1979), and continue today. One of the many interesting findings is that, although beauty is in the eye of the beholder, members of the public tend to have common perceptions of what constitutes natural scenic beauty (Zube 1976). One study, for example, measured how members of 26 different user, interest, and professional groups perceived 6 areas representing a cross-section of forest management in northern Arizona (Zube 1976). The most striking finding was the level of agreement in scenic preferences among these diverse groups. Taken as a whole,

these and related findings suggest that scenery is not just a strongly held value, but one held in common by a broad range of people.

Many people who hold value for the Basin's scenic resources realize that landscape settings are dynamic and that these settings may change over time whether humans alter them or not. People do not prefer to see drastic changes in the character or condition of geographic areas of importance to them (Galliano and Loeffler 1995). Resource managers are interested in the integrity of these landscapes, specifically about visual changes resulting from human alterations.

Supply of Scenery

In an effort to systematically inventory and protect the aesthetic quality of public lands they administer, Federal agencies have tested, adopted, and applied scenery management systems nationwide over the past quarter century. The ICBEMP measured the supply of scenery in the Basin using two related but distinct concepts, Landscape Themes and Scenic Integrity. The full analysis is described in Galliano and Loeffler (1995).

Landscape Themes—Every place within the Basin has an identifiable visual image that can be expressed in terms of a theme. Themes range from an essentially natural landscape such as a wilderness, to one that is highly developed such as an urban area. Themes indicate how people perceive the Basin's environments in a very general sense. Themes are images formed by combined landscape character (natural attributes) and scenic condition (human or cultural attributes). They are not goals for future management, but merely show what currently exists within a broad spectrum of degrees of naturalness or development. For the ICBEMP, landscape themes were defined based upon ecological subregions at the subsection scale. This scale provided the appropriate level of detail necessary for such a large assessment, yet remained fairly manageable.

The Basin's landscapes were described with five themes:

- Forest and shrub/grasslands (naturally evolving): Lands that have a vegetative cover of either forest species or shrub, forb, and grass species that are in a naturally evolving state or condition. Human intervention (such as manipulation or development) is at a very minimum or nonexistent level; natural processes dominate visually.
- Forestlands (natural-appearing): Lands that have a vegetative cover of forest species (large trees creating the walls and ceilings of visual space) that are in a natural-appearing state or condition. Human intervention may be evident or may have occurred, but does not dominate the natural landscape.
- Shrub/grasslands (natural-appearing): Lands that have a vegetative cover of shrub, forb, and/or grass species (small trees and plants that may create small walls of visual space, but an overhead plane or ceiling is absent) that are in a natural-appearing state or condition. Human intervention may be evident or may have occurred, but does not dominate the landscape.
- Agricultural lands: Working landscapes with geometric patterns that visually dominate the landscape, usually due to fencing and/or monocrop planting and cultivation patterns. The theme includes managed timber lands that have a cultivated appearance.
- Developed areas: Lands that have gridded street patterns, commercial areas, and suburban residential areas. These range from small developed areas with a gas station, a general store, or restaurant and surrounding homes, to larger towns or cities with gridded street patterns, commercial hubs, and numerous residential developments.

Naturally evolving forest and shrub/grasslands cover 7 percent of the area in the Basin; natural-appearing forestlands cover 37 percent; natural-appearing shrub/grasslands 30 percent; agricultural lands 20 percent, and developed areas 6 percent

Table 7.4—Existing landscape themes in the Basin.

Landscape Theme	Current Situation (hectares)	Current Situation (acres)	Percent of BLM- and FS-managed Lands in Basin	Percent of total Basin
Naturally-evolving forest & shrub and grasslands	3,913	9,666	10	7
Natural-appearing forestlands	21,561	53,256	46	37
Natural-appearing shrub and grasslands	17,826	44,030	34	30
Agricultural lands	11,540	28,503	8	20
Developed areas	3,632	8,971	2	6
Not classified	19	47	<1	<1
Basin Total[1]	58,491	144,473	100	100

[1]Total areas may be slightly different from other Basin totals because vector data from variable sources were used in this analysis.

(table 7.4). Current levels of landscape themes in the Basin lean heavily toward natural-appearing forestlands and shrub/grasslands. BLM- and FS-administered lands, as expected, contain higher proportions of less developed lands. Map 7.3 shows the primary landscape themes for the 394 ecological subsections in the Basin. Similar maps were generated for secondary and tertiary themes.

Scenic Integrity—This is a measure of the visual "wholeness" or intactness of the landscape (Galliano and Loeffler 1995). It was developed by combining data from the computerized Geographic Information System (GIS) on vegetative structure, landform, and road density. Scenic integrity was described using five categories, ranging from very high to very low:

- Very high scenic integrity: Settings where the landscape is visually intact with only minor deviations, if any. The visual harmony of the existing landscape character and sense of place is expressed at the highest possible level.
- High scenic integrity: Settings where the landscape appears intact. Scenic deviations resulting from human activities may be present but repeat the form, line, color, texture, and pattern common to the landscape's character so completely and at such scale as not to be evident.
- Moderate scenic integrity: Settings where the landscape appears slightly fragmented, but deviations remain visually subordinate to the "valued"[8] landscape character.
- Low scenic integrity: Settings where the landscape appears fragmented. Scenic deviations resulting from human activities dominate the valued landscape character. Scenic deviations are often unlike any natural occurrences within the landscape viewed.
- Very low scenic integrity: Settings where the landscape appears heavily fragmented. Deviations resulting from human activities strongly dominate the valued landscape character.

[8] "Valued" landscape character refers to scenic components that are expected and/or preferred by constituents and are obtained through questionnaires, interviews, and other survey techniques.

Map 7.3 - Primary landscape themes.

For the broad-scale assessment, scenic integrity was summarized by watersheds at the 6th field hydrologic unit code (HUC), which generally range from 10,000 to 12,000 acres, a scale consistent with that used by the agencies for viewshed analysis.

Existing scenic integrity was mapped for all lands within the Basin managed by the Bureau of Land Management, Forest Service, U.S. Fish and Wildlife Service, and National Park Service (map 7.4). Less than 1 percent of the acreage in the Basin was rated as very low in scenic integrity, 11 percent as moderately low, 38 percent moderately high, 31 percent high, and 14 percent very high. BLM- and FS-administered lands contain much larger proportions of acreage at the high end of the scale. Areas with the least alteration are located primarily in congressionally designated Wilderness and national recreation areas administered by the FS or BLM, or in unroaded areas. Unprotected and unroaded areas that have little alteration are the areas of scenic integrity at greatest risk from vegetation modification.

Demand for Scenery

According to the Resources Planning Act (RPA) 1990 program update, viewing scenery has a high participation rate relative to other recreation activities in the United States, with about 20 percent of the Nation's population and Basin residents participating. About 20 percent of the Nation's population and the Basin residents each participate in recreational activity. Although participation rates may change over time, it can be assumed that viewing scenery will remain among the highest ranked recreational activities in the Pacific Northwest.

Demand for natural-appearing landscapes is expected to outpace the demand for modified landscapes; Washington and Oregon State Comprehensive Outdoor Recreation Plans identified a need for nearly 19 million acres of natural-appearing landscapes to meet projected recreational demands by the year 2000, compared to about 5 million acres of heavily modified landscapes (FEMAT 1993). This demand is not limited to people who are only viewing scenery. Significant numbers of people who hunt, fish, and participate in other so-called "consumptive" recreation activities value scenery highly and choose where to recreate based not just on abundance of fish and game, but on scenic and aesthetic qualities (Allen 1988a, 1988b).

One component of scenic quality not captured by landscape themes or scenic integrity is air quality, which is important to people who hold value for places within the Basin. Clean air and good visibility contribute to the quality of life for people living in the Basin and may contribute significantly to the quality of the experience for people who come to the Basin to recreate or earn a living. Human perceptions of the scenic characteristics of a place are dependent on clean air. During most of the year, the vast majority of landscape settings within the Basin have excellent air quality. The Basin's relatively dry air, occasional cleansing breezes, and predominantly sunny days provide long-range views that are uncommon in other parts of the Nation.

Amenities and In-migration

The precise role of amenities in population growth, although a topic of much research, is not clear. There is increasing evidence, however, that the presence of amenities attracts both businesses and families to the Basin and its quality of life.

Recent studies and commentaries indicate an increasing importance of amenities in attracting and retaining businesses. For example, Rasker (1994) and Rasker and Glick (1994) discussed how the economy of the Yellowstone Ecosystem had dramatically changed. Rasker and others (1994) concluded that both long-time business people and those who have recently moved to the region claim amenities to be important reasons for staying in or moving to the area. A survey of residents of the 100-county ICBEMP assessment area (Rudzitis and others 1995) found that reasons other than employment, including landscape, scenery, and outdoor recreation opportunities, were important in people's decisions to move to the Basin.

Map 7.4 - Scenic integrity classes.

Rudzitis and Johanson (1989) link population growth in the northern Rocky Mountains to the presence of Wilderness Areas, noting that people often cite "wilderness" as an attraction in making decisions on where to relocate. Wilderness Areas, present in 46 of the 100 counties in the Basin, total 10.3 million acres. National Recreation Areas, National Parks, and other areas administered by the National Park Service are located in 28 of the 100 counties and total 3.3 million acres. Table 7.5 shows the amount of acreage of these protected areas in the 10 fastest-growing and 10 stable or declining counties in the region. These data support, although not conclusively, the notion of wilderness as a factor contributing to in-migration.

Economic development in the region increasingly depends on environmentally based amenities. This kind of economic development does not depend on the environment for raw materials, but rather establishes a quality of life dependency important in retaining and attracting a labor force. Factors other than traditional site-selection criteria become important considerations. Service- and knowledge-based industries, which comprise most of the national economic base, are relatively "footloose," meaning their location is relatively independent of natural resource commodities. While the Basin's economy is relatively more dependent on agriculture and manufacturing compared to the Nation as a whole, the fundamental changes occurring nationally are mirrored in the Basin. The growing reliance on information, services, and transfer payments as the economic base of the region suggests that quality of life factors will gain in importance in business location decisions.

Environmental quality factors such as clean air, pure water, the presence of recreation areas, wildlife, and appropriate balances between development and open space can constitute economic assets, acting to retain existing people and business, and to attract potential entrepreneurs (Rasker 1994).

The environmentally oriented lifestyles that outdoor recreation resources provide are important to people living in the Basin, as well as for attracting migrants. This lifestyle is difficult to describe but generally consists of an outdoor orientation; relatively easy access to the region's undeveloped forests, mountains, rivers and wildlife; and appreciation of the relatively clean air and water and open spaces of the Basin. One measure of this interest is the relative rate of participation in outdoor recreation, which as described in chapter 6 is significantly higher among Basin residents than among people living in other regions of the nation.

Rasker (1994), Power (1994), and others have emphasized the role of a high quality natural environment, scenic beauty, and recreation opportunities in influencing population growth and shaping the emerging economy of the Basin. For example, Rasker (1995), writing about the Basin, stated that:

> *As we approach the twenty-first century, there is a striking change in how the region's forests, mountains, streams, rivers, and grasslands contribute to the economic life of its residents. Once, settlers were attracted to the region by the promise of logging, ranching, mining, and farming. Now, the magnet that draws new residents and holds the region's existing inhabitants is environmental quality: clean air and water, handsome scenery, and native wildlife...the region's economy is growing less dependent on resource extraction and more dependent on less tangible qualities: environmental quality, education, entrepreneurship, and capital.*

While there is clearly a need for additional research about environmental factors relative to social assessment, the available research indicates a growing importance of environmental amenities in migration and business location decisions.

Implications for Ecosystem Management

Environmentally based amenities managed by the Federal Government play many social and economic roles in the Basin; they contribute to the quality of life of Basin residents, attract new migrants, and provide recreational settings for residents and non-residents. Despite the importance of amenities, such as recreation opportunities and scenery, systems to map and inventory these values are not well integrated into current agency planning systems at ecoregion scales.

Table 7.5—Wilderness acreage for the 10 fastest growing and 10 stable/declining rural counties in the Basin.

County	1990-94 Growth Rate	Wilderness Acreage	Percent of County
Growth Counties:			
Boise, Idaho	28.2	66,273	5.4
Kootenai, Idaho	25.5	0	0.0
Valley, Idaho	25.0	722,905	30.2
Teton, Idaho	24.1	0	0.0
Ravalli, Montana	22.8	286,700	18.7
Deschutes, Oregon	21.3	108,400	5.5
Elko, Nevada	20.7	0	0.0
Bonner, Idaho	19.8	89,455	7.3
Humboldt, Nevada	18.8	0	0.0
Adams, Idaho	18.2	22,437	2.6
Stable/Declining Counties:			
Silver Bow, Montana	2.6	0	0.0
Lake, Oregon	2.0	18,119	0.3
Columbia, Washington	1.9	79,787	14.3
Grant, Oregon	1.1	186,155	6.4
Madison, Idaho	0.3	0	0.0
Whitman, Washington	0.2	0	0.0
Harney, Oregon	-0.1	0	0.0
Shoshone, Idaho	-0.4	0	0.0
Deer Lodge, Montana	-0.5	56,231	11.8
Custer, Idaho	-3.6	382,508	12.1

Assuming the population continues to increase with in-migration, there will be a multiplying effect on demand for recreation opportunities resulting from the changes in population and lifestyle. Area residents may find themselves increasingly in conflict with nonresidents who also find amenities within the region attractive as places to recreate, thereby accelerating potential conflicts with the tourism industry. As lifestyles change and the population ages, recreation demands are expected to shift from consumptive types of recreation to the more appreciative experiences.

The data on recreating participation by lifestyle, coupled with projected population increases, also suggest a multiplying effect on demand for outdoor recreation opportunities traditionally found on Federal lands within the Basin. These increases may intensify long-held conflicts, not only between recreation and commodity uses, but among recreation activities as well.

The lack of both uniform Basinwide data on the supply of recreation opportunities and a field-based inventory of existing scenic condition hampers efforts to assess the extent to which Federal agencies can meet demands for important social values. To address increased demand for amenities, such as

recreation and scenic quality, land management agencies may find it helpful to accelerate their inventory processes, map areas, and use GIS technology for integration of these data with other natural resource information.

Changes in the region's economic structure and the growing importance of amenities and quality of life considerations in business location decisions create challenges to traditional economic development models that are based on natural resources. The forest and range, while still sources of commodities, are also sources of environmental amenities upon which many local economies are increasingly dependent. Amenity-rich areas will likely continue their role as centers of growth, increasing the need for intergovernmental cooperation and coordination in growth management to mitigate impacts.

Assuming the Basin will continue to have not only increasing numbers of people, but at least relatively constant recreation participation rates and an overall aging population, demand is expected to increase for high quality, nature-dominated scenery within the Basin. While some developed portions of the Basin will continue to offer outstanding scenic landscapes, the greatest opportunity for meeting expected increasing demand for scenery in the Basin lies in the amount of undeveloped and partially developed settings.

An emerging opportunity already being capitalized in the Basin is ecotourism. Ecotourism is a special type of tourism, having some of the same characteristics as tourism: people leave their home, travel to a recreation setting, engage in a package of activities designed to produce a desired set of experiences, and, presumably, return home with a set of benefits. Adding the "eco" prefix defines tourism more sharply:

- The natural environment is the central attraction.
- Any development is designed to provide better access to, and awareness of, the main attraction.
- It is active participation and appreciation (for example, participating in an archaeological dig), rather than passively watching someone else do something in a classroom setting.
- There is an element of adventure and romance.
- People learn interesting aspects of the natural and cultural environment through outdoor recreation.
- The tourism opportunity fits well into the existing ecosystem.

Ecotourism opportunities must be sustainable socially, economically, and environmentally. For example, the tourism opportunity is developed in concert with, and supported by, local and regional residents. The tourism opportunity is financially self-sufficient; earned revenues or other sources of financial support cover all capital and operations costs over the long term. Local and regional economics benefit from increased numbers of tourists and associated expenditures. Two primary goals of construction, management, and visitation associated with tourism are to minimize energy usage and encourage all people involved with the tourism opportunity to be environmentally sensitive.

Several current recreation issues were identified from the most recent Statewide Comprehensive Outdoor Recreation Plan (SCORP) for each of the four main states of the Basin. Issues common to all areas of the Basin include:

- Cooperation and coordination among land management agencies.
- Funding.
- Maintenance and development of facilities.

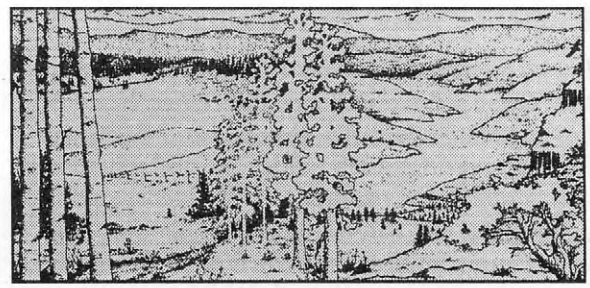
Several other common issues, though not among all state SCORPs, include access, education/information, and liability.

Restrictions on use levels and visitor behaviors are increasing as pressures increase on finite resources such as wilderness trails located near population centers or to which access is good. Limiting visitor numbers through some kind of rationing and allocation system is usually viewed as a last resort for resource protection. Any recreational use has

some impact on the natural and social environment; the question is what types will be acceptable, and to what extent and how. Managers of Wilderness Areas, Wild and Scenic Rivers, and other resources where protection of the environment and quality of the experience are paramount often conduct studies to determine a balance between recreational uses and impacts.

Because impacts tend to be more a function of visitor behavior than amount of use, it is important in devising programs for habitat restoration to understand what aspect of recreation use is causing impacts, make decisions about what levels and types of impacts are unacceptable (Stankey and others 1985), and suggest appropriate remedial mechanisms. Unfortunately, there is little research documenting the impact of recreation use on key ecosystems such as riparian and aquatic habitats. The lack of research hampers the ability to develop appropriate, scientifically based actions to restore habitats, particularly for threatened and endangered species and for anadromous and inland freshwater fisheries. For example, interim direction for management of anadromous fisheries in the region (PACFISH) suggests closing many recreation sites located in riparian areas. Such closures would have dramatic impact, particularly on camping opportunities, because people prefer to camp near water. Closer examination of the relationship between recreation and impact on fish and riparian habitats would help managers better understand the costs and benefits of such proposals.

Perhaps the biggest recreational issue is financial. Without investment in recreational resources and facilities, the supply and quality of recreation opportunities will decline as population levels increase within the Basin. FS and BLM budgets for recreation are declining, making it difficult to adequately staff and maintain existing facilities and settings. While reduced Federal staffing and maintenance can inspire a spirit of volunteerism, providing many benefits to agencies, user groups, and the public, relying on volunteers may not be a sustainable strategy.



Programs that charge the public for recreation on public lands may be one answer. Research suggests that people are willing to pay as long as fees are reasonable, equitable, and are used to improve recreation at the site. Agencies should pay careful attention to the cumulative impacts of fee systems.

Federal land managers are contracting increasingly more recreation operations, from large-scale recreation and wilderness planning efforts to management of campgrounds and reservation systems. Information gathered from observing the private sector in providing recreational opportunities on public lands can be used to develop new programs. However, there appears to be a large, growing gap between the value of recreation on public lands and the ability of the FS and BLM to successfully accommodate demands for recreation opportunities.

ROLE OF THE PUBLIC IN ECOSYSTEM MANAGEMENT

A basic tenet of ecosystem management is that people are active and involved in all phases of planning and decision-making (Jakes and Harms 1995). This is a common theme in the ecosystem literature, expressed in terms such as partnership, collaboration, consultation, involvement, power-sharing, and participation (Grumbine 1994, Lee 1993, Moote and others 1994).

The underlying goals of public participation include not just informing the public and soliciting opinions on proposed actions, but integrating people's concerns into decisions responsive to the public. Public participation can bring together the multiple partners involved in ecosystem management in settings where common goals can be identified and a basis for negotiation can commence.

Because public values are not static, public participation helps managers understand changing public needs. This information, coming in the form of interactive processes, can help institutions such as the BLM and FS to stay updated in both the issues addressed and the mechanisms employed to resolve them (Stankey and McCool 1995). This is especially true for ecosystem management, which strives to respond to an evolving set of social values. Social change is rapid; institutions and processes must be adaptable and sensitive to public needs to stay relevant (Moote and others 1994, Stankey 1994).

Another challenge for public participation is that society's demands on natural resources have diversified. There has been a significant shift in emphasis from commodity uses of public lands to amenity and cultural uses, which are difficult to define in strictly economic terms (Gale 1991). Instead of a simple planning problem of one objective, there are now multiple and frequently competing objectives. In the words of Allen and Gould (1986), managers are confronted with "wicked" problems that cannot be solved through mathematical models. Public participation in planning can help articulate what noncommodity and commodity values are important, and to whom.

Interaction with affected publics can help managers understand the various values and definitions of ecosystems that exist in the population and identify the distribution of preferences about public land management. People who know the land best are valuable sources of information. Friedmann (1973) argues that action in society requires actors at all levels with different types of knowledge. He presents a case that experiential knowledge is as valid and useful in providing a basis for action as more formal and systematized forms of knowledge. Likewise, Yankelovich (1991) argues that public judgment is a useful form of knowledge. The role and use of local knowledge in science and management processes, however, is not defined consistently.

Current Public Participation Efforts

Public participation in the ICBEMP is guided by the National Environmental Policy Act, National Forest Management Act, Federal Land Policy and Management Act, their guidelines, and other laws that contain legal requirements for incorporating public input into natural resource decision-making. For example, in situations where an environmental impact statement is required, NEPA requires an early and open process to facilitate free and open communication with the public. At a minimum, this process includes scoping to identify issues that should be addressed and a public comment period after a draft document is issued. Although agencies frequently do more, such as providing opportunities for comment at additional stages of the planning process, they have less commonly involved members of the public in implementation and monitoring.

A recent Forest Service report (USDA Forest Service 1994) stated that the public has "high expectations as to the degree of influence it can have on natural resource management." This expectation was confirmed by the CRB survey in which the public was queried about preferred level of participation in planning (Brunson and others, n.d.). The results were uniform across respondents; the greatest support was for acting as a full and equal partner (chosen by 32% to 39%), followed closely by serving on advisory boards (chosen by 30% to 32%). Providing suggestions and letting the public make decisions was chosen by roughly equal numbers (about 10% to 18%), and no public involvement (letting resource professionals decide) was chosen by just 1 to 3 percent.

People are also concerned about the efficiency of public participation. During EIS scoping and subsequent requests for comments, many members of the public said they valued being asked for their knowledge and opinions in a balanced, representative way, but worried that while time was being spent talking, nothing was happening on-the-ground.

Many collaborative groups have formed in the past few years to jointly address natural resource issues. Wondolleck and Yaffee (1994) conducted an extensive study of what they called "building bridges" that give examples of increased collaboration between the Forest Service and other public land stakeholders. These included many well-known efforts that took place in or adjacent to the Basin: Applegate Partnership, Blue Mountains Natural Resources Institute, Nooksack River Partnership, Tonasket Citizens Council, Yakima Resource Management Cooperative, New Meadows Community Outreach, and Willamette Forest Plan Implementation Monitoring.

The authors surveyed Forest Service employees and nonagency personnel to develop 35 case studies as models for building bridges. The report was designed to identify and analyze success stories that could be emulated and supported within the Forest Service. Each case study was structured to show why the situation was perceived as a success, why success was possible, how barriers were overcome, and what lessons were learned for future bridging. The case studies show how building bridges can:

- Provide powerful examples of the benefits of creating a more permeable membrane between agencies and the public.
- Allow agencies to acquire needed information from the public.
- Generate good resource decisions that will endure.
- Build support for forest management decisions.
- Influence public knowledge and values.
- Broaden the workforce available to accomplish activities on-the-ground.
- Make the agency a better neighbor.

The BLM has created or been involved in similar efforts, such as the Trout Creek Working Group in eastern Oregon.

The report also listed factors contributing to success, such as accepting nonagency participants as full working members; involving dedicated and open-minded individuals; and having required resources, capabilities, and support. Recommendations for future efforts included ways to communicate images of successful bridging, enable employees to build and use bridging arrangements, and encourage employees and nonagency interests to build relationships.

These results demonstrate the public's clear interest in having a greater role in natural resource decision-making. This interest takes many forms, from confrontational arguments that Federal lands should be taken away from the Federal Government entirely, to seeking influence on public land management through grassroots consensus efforts. One example of the latter was the Forest Ecosystem Stewardship Demonstration Act of 1995 proposed by the Flathead Forestry Project, an ad hoc group of conservationists, loggers, small mill owners, and civic leaders in northwestern Montana. This act, introduced into the House of Representatives by Representative Pat Williams of Montana on May 25, 1995 (HR 1682), encouraged the Forest Service to utilize stewardship contracts to accomplish ecosystem restoration in conjunction with logging projects. The proposal included local forest stewardship councils, consisting of public groups that would provide local advice to the Forest Service.

Another recent example of grassroots participation is the "cow cops" program instituted by the Oregon Natural Resources Council. This program reflected how citizens with a special interest can assume responsibility for certain types of planning, implementation, and monitoring tasks. Volunteers carrying copies of allotment plans inspected FS and BLM grazing allotments periodically and reported violations to the respective agency. This effort was spurred by public perceptions that the agencies either would not, or could not, adequately monitor range conditions. The reaction of ranching groups to the volunteer monitoring program was negative, leading to a confrontational atmosphere (Cockle 1995).

A final recent example was a forum on "Dynamics of Northern Idaho Forests" held February 2 and 3, 1996, in Coeur d'Alene, Idaho. Sponsored by various agencies, organizations, industries, and tribes, the symposium was designed to assemble information about the plants, animals, and people of the region and how they interact. This symposium also indicated a scale of analysis viewed as appropriate by diverse interests. Similar local and regional efforts are expected to be scheduled in the future as residents of communities, trade regions, or socio-ecologic regions decide it is time to work together to identify and seek solutions to public land management issues and conflicts.

A related issue for the agencies is how to blend increased opportunities for public participation with the emerging role of science as a pillar of ecosystem management. Public opinion polls have found support for scientific solutions to natural resource problems. Scientists are receiving increasing requests to address and provide information on complex ecological issues and have helped society gain an appreciation of the complexity of human interactions with the environment. However, allocation of resources is inherently a process of judging the relative worth of differing perspectives on natural resources. Science, while assisting in mapping and measuring a variety of values and identifying consequences of alternatives, has a limited role in the allocation process. Although science can provide information about existing social, physical, economic, and biological conditions and processes, their interrelationships, and likely response to change, science cannot dictate how public lands should be managed. That decision is a social and political issue, not a scientific one.

The role of science provides a tripartite combination of expertise to natural resource managers: scientists who measure, analyze, and display data; managers who use such information to make

decisions, and publics who interact with both scientists and managers. Because this forum has been tested in few natural resource situations, however, the roles, processes, and expectations are still forming. The ICBEMP demonstrated one attempt to open up scientific analyses to the public.

Recent Agency Initiatives

The Northwest Forest Plan's creation of Province Advisory Committees was a move toward a new approach to public participation. Each of the 12 provinces created as management units for the plan has an advisory committee comprising federal employees and members of the public. Several of these committees address management of lands that extend to the east side of the Cascades.

Ecosystem assessment at the watershed scale provides an additional avenue for agencies to work with diverse members of the public. The process of inventorying social, physical, biological, and economic conditions in relatively small-scale watersheds calls for both local and scientific knowledge. Because the public's role in these analyses has not been consistently monitored, the effectiveness of this approach to public participation is unknown; additional public incentives may be needed to encourage fuller and broader participation.

The Northwest Forest Plan also established 10 Adaptive Management Areas (AMAs), designed to encourage development and testing of technical and social approaches to achieving desired ecological, economic, and other social goals. The AMAs, which range in size from 84,000 to 400,000 acres, have a clear objective for public participation: "These areas should provide opportunities for land managing and regulatory agencies, other government entities, nongovernmental organizations, local groups, land owners, communities, and citizens to work together to develop innovative management approaches" (FEMAT 1993).

A 1994 mail survey of residents of the Central Cascades AMA found that people highly valued citizen participation in forest planning, even if greater costs were incurred (Shindler and others 1995). Respondents favored an active role for the public, including serving on advisory review boards and, to a lesser extent, acting as full and equal partners with Federal agencies. This survey is consistent with the results of other recent research, as well as the many grass root efforts discussed.

Another recent initiative began in 1995, when the BLM and FS established Resource Advisory Councils (RACs) in the portions of Washington and Oregon not already covered by province committees. The RACs, also formed under the Federal Advisory Committee Act, parallel the intent of Province Advisory Committees. Unlike province committees, RACs do not include federal employees as members, although agency employees attend all meetings. RACs are an outgrowth of the BLM Districts' Multiple Use Advisory Groups, but have greatly expanded scope. Because RACs were one of the few aspects of Rangeland Reform/ Healthy Rangelands initiatives allowed to proceed, they will not be unique to the Basin.

The RACs make recommendations to the FS and BLM on ecosystem management, watershed planning, and other local or regional natural resource issues. The list of objectives for Resource Advisory Councils, taken from the Draft 1784 Handbook on Advisory Committees dated March 20, 1995, includes:

- Collaborating in resource management across jurisdictions.
- Promoting partnerships and working groups to develop regional solutions to management issues.
- Assisting with educational efforts.
- Sharing science and other information.
- Encouraging and supporting local groups to implement ecosystem management.

The Province Advisory Committees and the Resource Advisory Councils were asked by the ICBEMP Executive Steering Committee to provide comments on a preferred alternative for the Eastside and Upper Columbia River Basin EISs. It remains to be seen how successful these groups will be at forming bridges between agencies and the public. Monitoring the effectiveness and efficiency of these and other public participation efforts, using criteria based on those suggested by Wondolleck and Yaffee (1994), can provide the information needed to measure their success.

Implications for Ecosystem Management

One ecosystem management function may be to clarify the role of the public in public land management. It is clear that the public is assuming a more active role in public land management, whether or not the opportunity is provided by the Federal Government. People want various roles in decision-making and assurance that their concerns are heard and treated fairly. Societal debate over the appropriate institutions for public participation will continue.

Natural resource agencies frequently find themselves in situations where goals of resource management disagree with various potential futures described by conflicting groups. In addition, there is often little agreement about cause-effect relationships; forest health is an example of a debate among scientists about the causes and effects of forest decline. Another example is the continuing debate among social scientists about the role of resource commodity flows in issues of community stability and resiliency.

In these situations, collaborative learning processes (Krannich and others 1994) may be more suitable for planning than other techniques. Public participation procedures for ecosystem management could focus on learning, recurrent interaction among participants, and increased opportunities for working through complex problems to identify possible solutions. Krannich and others (1994) said, "No one party, including any agency, organization, or discipline, holds the key to understanding a particular natural resource management situation." They believed that successful design and implementation of ecosystem management policies requires parties to be open to learning from each other and to acknowledge that interactive learning is an ongoing process.

Collaborative learning is based on several assumptions:

- Learning is more likely in active, rather than passive, situations.
- People learn in different ways.
- Learning styles vary.
- Active learning groups can engage conflict and controversy.
- Systems thinking fosters learning.

Collaborative processes based on concepts of dialogue and mutual learning (Friedmann 1973) seem to be appropriate for the kinds of planning situations confronting natural resource managers. Traditional forms of rational-comprehensive planning, where public participation is limited to identifying issues and responding to a draft document meeting the National Environmental Policy Act, may not be viewed by the public as adequate. An institution that provides ongoing opportunities for public-agency interaction, and into which individual projects will flow, may have the greatest chance for success.

As a result of effective public participation and mutual learning, the resulting decision, in theory, should have greater social acceptance. Salwassar (1990) defined the primary goal of "New Perspectives"[9] as developing a "scientifically sound and socially acceptable practice," a statement equally

[9] New Perspectives was a management direction established by the Forest Service in 1990 for the forestry program; its two basic principles were to manage forests to balance values and produce a sustained supply of goods and services; and to maintain biodiversity (Stankey and Clark 1992).

true of ecosystem management. The role of public participation in this context is to provide a forum for developing common social norms and expectations about ecosystem management. Public participation in ecosystem planning therefore helps decision-makers understand the feasibility of potential actions.

In addition to the foundation of collaborative learning, numerous studies have suggested principles for enhancing public participation processes that ecosystem management would be wise to consider. For example, previous researchers suggested a four-phase approach to public participation:

Phase 1: Create an environment for meaningful public involvement.

Phase 2: Initiate a participatory decision process.

Phase 3: Conduct an open decision process.

Phase 4: Complete a successful shared decision process.

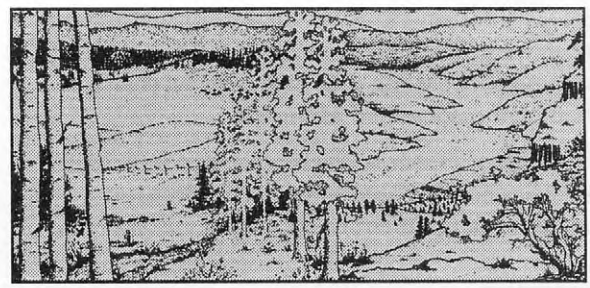
McCoy and others (1994) identified the following specific principles to guide public participation in ecosystem assessment and management processes:

- Clearly state goals and objectives.
- Plan for effective dialogue.
- Build cooperation constructively and deliberately.
- Emphasize education and social learning.
- Diversify the public involvement framework.
- Be open, honest, and responsive.
- Understand the multiplicity of publics and techniques.
- Use a third-party intervener when necessary.
- Establish a framework for continuing dialogue.
- Analyze, evaluate, and monitor.

Roles and expectations must be clearly articulated for public participation to be successful. Among the expectations that should be communicated are the role of the public, the use of public input, and methods of using and acknowledging that input. Follow-through is especially important. It is one matter to provide opportunities for public input, and yet another to provide feedback on how that input was used and what the continuing role of the public will be, not just in planning but also in implementation. The process for incorporating traditional environmental knowledge held by the public needs to be made explicit.

The concept of bridging appears to have many social benefits. Wondolleck and Yaffee (1994) identified successful bridging, claiming two important aspects related to success were encouraging public understanding of other groups' interests and needs and promoting interagency cooperation. Some success characteristics could be measured by outcomes, such as generating a better information base to help make resource decisions or creating greater public ownership in a project or decisions. These criteria could serve as an initial set of indicators that could be monitored to determine the success of future public participation efforts. Another benefit could be increased predictability in resource outputs and conditions; public participants could gain a better understanding of the issues, likelihood of implementation, and other information that helps them to be better informed and able to anticipate changes. Predictability of resource flows is a key public issue, and one on which the agencies have a mixed track record.

Another consideration for public participation in ecosystem management is the issue of scale. Krannich and others (1994) suggested setting standards and guidelines at the bioregional level, then developing implementation strategies at the more localized project level. However, public



discussion about the transition to ecosystem-based management in the Basin was recommended at the scale that most people connect to the land, which is the local, not the bioregional scale.

Scales of analysis utilized by the ICBEMP included ecological reporting units, economic trade regions, 4th field watersheds, groupings of 4th field watersheds, 6th field subbasins, groupings of counties, groupings of communities, EIS planning areas, the assessment area, and the Nation. The appropriate scales and the role of the public at each level needs to be discussed further. Although methodologies of obtaining local, regional, and national participation should be explored, this issue is sensitive. For example, national conservation organizations have objected to what they perceive as an overemphasis on local input into decisions about public land management.

Finally, monitoring public participation is a key element of measuring success. Moore Information, Inc. (1994) identifies at least five different ways to measure success, including product, politics, interest, responsibility, and relationship orientations. While the obvious intent of planning is to achieve product-oriented success (getting a plan completed and implemented), other forms of success may also be important in a planning exercise. Traditional measures of success typically include number of meetings held, attendance numbers, and the size of mailing lists. However, these are measures of opportunity, not success. True measures include not just the social acceptability and desirability of the outcome, but participants' evaluations of the process, their role and its effectiveness and efficiency, and perceived levels of ownership in the ultimate decisions. According to Krannich and others (1994):

> *It is not merely computers full of social indicator data, GIS maps, or species distributions and habitat effectiveness trends that will determine the success or failure of ecosystem-based management. Rather, it will hinge on whether or not we are able to craft policy mechanisms within which we can mix that scientific information, assign it meaning, sort it out, and then chart a course for ourselves...the participants themselves—both in and out of agencies—are ultimately responsible for the outcome and are the judges of its adequacy.*

WORKING TOGETHER: INSTITUTIONAL COMPONENTS OF ECOSYSTEMS

Institutional analysis allows the story of the Basin to be told from the perspective of organized interests, providing insight into the forces at play in decision-making and the relationships among groups in policy development and implementation. Institutions represent our collective experiences, and it is through institutions that humans solve social problems (Cortner and others 1995). Gary Machlis, lead social scientist for the National Park Service and a University of Idaho professor, described institutions as "collective approaches to solving collective problems."

The importance of institutions to ecosystem management was described by Lee (1994): "Managing ecosystems is an inherently institutional task, because the ecosystems that matter are already exploited by human institutional arrangements, and changing the way that humans interact with ecosystems requires changing institutions." There are multiple ways to consider institutions: as formal organizations; durable social arrangements that guide or control actions; or any social creation that embodies a purpose. The defined bounds of institutions are quite fuzzy (Lee 1994).

In this social assessment, institutions are defined as by Ingram and others (1984): "Legal, political, and administrative structures and processes through which decisions are made with respect to public policy." This definition is a middle ground, accepting a broad but not extensive interpretation of institutions, including organizations such as government agencies as well as formalized patterns of agreement such as property rights. Not included in this description are less formalized patterns such as political beliefs and finer-scale institutions such as human families.

Structure of Government

To link the biophysical, economic, and social interests of citizens into a coherent management strategy, ecosystem management must address implementation methods of such strategy in an institutional environment that is highly fractioned between different organizations and interest groups. The structure of government in the United States has been termed "federalism," a system characterized by the conscious division of powers among governmental units, with coordinate and independent governments legitimized on a constitutional basis (Diamond 1981). The most important of the government units on the national scene are the one federal and 50 state governments; however, local governments (which are technically dependent on the states for authority) exert a surprising amount of autonomy (Sokolow 1987). Local governments include not only county and city governments, but quasi-governmental bodies such as school districts, port authorities, irrigation districts, and a host of others. (The role and status of tribal governments are discussed earlier in this chapter.)

At the Federal and State levels, the executive, legislative, and judicial branches of government provide sometimes discrete but often overlapping functions. The authorities between branches and levels of government are often unclear, due in part to the ambiguity of the Constitution. The division of government results in many opportunities for informal influence over the formal decision-making process, as demonstrated by the existence of thousands of corporate and noncorporate lobbying

groups (McLain 1995). Interest groups operate at whatever point of entry believed to be most effective and concentrate their resources according to their own track record of success.

The Federal executive, legislative, and judicial branches have all been highly active in natural resource management issues during recent years.

Executive

Legal authority to manage and protect natural resources is generally vested with governments, which in turn, assign operational responsibilities to their respective bureaucracies. Bureaucracies are institutions within government that provide a mechanism for consistent policy implementation (Shannon 1994). Several studies have found, however, that the possession of formal authority is distinct from control (Bachrach and Baratz 1970, Kingdon 1984, and Lukes 1974). As McClain (1995) observes:

> *One can have no formal decision-making authority whatsoever yet still exercise considerable control over policy choices provided one controls the processes by which issues become perceived as public problems, the ways in which problems are defined, and the selection (or elimination) of possible solutions.*

Although bureaucracies follow the principles described by Weber (1946) for established rules, written records, and professionalism in the attainment of organizational goals, the bureaucracies are subject to considerable outside influence. The dependency of bureaucracies on political support subjects them to influence from organized interests, as described in earlier text. Members of the bureaucracy may resist efforts for coordination and sharing of authorities (Balmer 1990) if loss of stature is anticipated.

The BLM and FS exist within a system of other federal agencies in various departments that also have management and/or regulatory authority for ecosystem components, and in some cases, a mission with a narrower focus. Regulatory agencies, such as the Environmental Protection Agency, U.S. Fish and Wildlife Service, and National Marine Fisheries Service, have overlapping responsibilities that have potential to conflict with the multiple-use mandates of the BLM and FS; this situation often makes it difficult for the BLM and FS to simultaneously respond to the concerns of these regulatory agencies and the concerns of other agencies, governments, organizations, and individuals. This difficulty is not unique to the BLM and FS; the debate in recent years about the future of salmon in the Pacific Northwest, for example, has been complicated by the numerous agencies, committees, and governments that each have their own authorities, scientists, and perspectives on issue resolutions.

Legislative

The Congress has become highly active in mandating specific BLM and FS actions over the past decade (Jones and others 1995). Although many different pieces of national legislation, including the Endangered Species Act of 1973 and the Wilderness Act of 1964, affect natural resource management in the Basin, basic legislation affecting both the FS and BLM [the Federal Land Policy and Management Act (FLPMA) and the National Forest Management Act (NFMA)] created broad agency mandates that have saddled the agencies with conflicts:

> *The American system of the separation of powers requires Congress to provide fairly specific guidelines lest the courts declare overly broad or vague statues, as unconstitutional delegations of legislative power. Yet, of necessity, statutory requirements mandating multiple uses are susceptible to many interpretations... Administrators were assigned not only the responsibility of developing the technical details but also the task of dealing with conflicts unresolved by Congress, and probably unresolvable to everyone's satisfaction. At times, this has overwhelmed the agencies and their technical capabilities and, perhaps, gone beyond the limits of their constitutional authority (Balmer 1990).*

In this institutional climate, agency actions frequently become controversies that require political solutions. The Congress has responded with additional and sometimes contradictory legislation to address these issues, but informal methods of influence are likely the most important form of congressional oversight (Congressional Quarterly 1991). In other words, Congress can, and does, put direct pressure on land management agencies through "lobbying" agency staff. By communicating the desires of either their constituents or the interest groups that provide political support, congressional representatives are able to direct agency actions outside of the legislative process. Agency personnel, ever aware of anticipated reactions (Culhane 1981), adjust their behaviors accordingly.

Perhaps the most important legislative responsibilities of the Congress are the drafting and passage of appropriations bills, the "power of the purse" that is the life blood of government operations. The Interior and Related Agencies Appropriations Bill provides funding for both the FS and BLM, frequently carrying direction for agency operations (Bolduan 1990). It has become common practice to attach amendments to this appropriations bill and others to determine public policy. A recent example was passage of the 1995 Recessions Act (P.L. 104-19), which contained the Taylor-Dicks Amendment, a salvage sale rider prescribing how the Forest Service would address the aftermath of the major forest fires of 1994. This rider had sufficiency language overriding major environmental legislation that previously had ensured opportunity for citizen appeals of land management operations. Appropriations language with limitations on judicial review of Forest Service operations had occurred several times in the past decade prior to the Taylor-Dicks Amendment (Jones and others 1995). Although the Ninth Circuit Court ruled that the Taylor-Dicks Amendment was an unconstitutional violation of the separation of powers doctrine, the Supreme Court overruled the decision (*Seattle Audubon Society v. Robertson*, 112 S. Ct. 1407, 1992).

Judicial

The preceding case is one example of increasing judicial involvement in natural resources. The power of Federal judges is considerable, as they possess authority to stop any administrative action by issuing writs of injunction. Although these powers are absolute, the courts have acknowledged that agencies retain responsibilities to carry out actions to implement public policies, giving the agencies greater flexibility and autonomy that appears to be supportive of ecosystem management (Meidinger 1995).

Review of Forest Service-related litigation and administrative appeals between 1971 and 1993 (Jones and Taylor 1995) found markedly increasing use of litigation as a means to address grievances. Environmental groups had more than double the complaints of commodity interests. Although the agency won the majority of these legal challenges, the authors concluded that "the courts and administrative appeals process have likely been significant factors in catalyzing change within the Forest Service." The prospect of legal and administrative challenges force agency personnel to alter or constrain plans in advance of decisions to avoid the high cost of legal conflicts. Decisions about planning, implementation, and monitoring have the potential to shift from what is best for the ecosystem, to what can be successfully appealed.

The strategy to utilize litigation as a tool to influence policy carries a cost, however, because legal and administrative challenges hinder the ability of agencies to carry out their management programs, leading to the characterization of government "gridlock." These challenges also damage cooperative working relationships among those who may be important to the implementation of management actions and frequently exacerbate tensions surrounding difficult public policy issues.

Cross-Jurisdictional Strategies

Although the above summary appears to indicate that many key issues of authority have already been decided, a divided government continues to provide multiple pathways through which advocacy groups may pursue their interests. The courts, the bureaucracy, and the Congress are all likely to remain involved in the evolving policy disputes about natural resources.

The FS and BLM operate within a complex institutional environment challenged by definition and implementation of ecosystem management. Understanding the options available for operating within this environment is a precursor to developing cross-jurisdictional strategies required to manage entire ecosystems. This need was considered in the following review of three common models of decision-making, policy formulation, and previous examples of cross-jurisdictional approaches to natural resources management, which give emphasis on collaboration with states and counties.

Policy Formulation

In an examination of how ecosystem management may operate in the American federalist system, McLain (1995) outlined three approaches to policy formulation:

- The *market politics model*, which promotes maximizing individual satisfaction through assignment of values to individual preferences. Government bodies are engaged only to assure open access to the process and to ensure proper procedures are followed.
- The *adversarial interest group model* which, like the market politics model, continues to view society as a free market, but one in which participants operate in groups to advocate for their interests. Government's role is largely to create the proper settings for the interest groups to interact, and policy makers select the option that satisfies the largest number of groups.
- The *participatory democracy model*, which looks for shared interests among stakeholders. Governments take an active role in facilitating the exchange among individual and group interests to develop a common vision for future actions.

McLain concluded that the participatory democratic model has the best opportunity to advance ecosystem management because, unlike the other models, it allows for identifying shared purposes across governance levels. It provides opportunity for social learning, a critical feature in addressing complex natural resource problems (Lee 1993). McLain also recognized the considerable challenges in creating this common vision in the Basin relative to the diversity of land ownership categories, multiple layers of political authority (which are further fragmented internally), and uneven distribution of resources, including knowledge and capital. However difficult it may be for the participatory model to be implemented, McLain emphasized that the other major models of policy making cannot provide an appropriate framework for addressing cross-jurisdictional issues because their structures lead to social division rather than social cohesion.

Previous Cross-Jurisdictional Efforts

Smith and others (1995) examined 12 case studies of cross-jurisdictional management efforts across the United States. They emphasized that institutions must be capable of learning from past actions and experimental behaviors if the participatory model is to succeed, and that much remains to be done to structure institutions to foster this learning. They concluded that tolerance for change is critical, suggesting an approach that emphasizes incremental changes and places authority for managing change with those most directly affected. They called for open information flow, saying that the success of ongoing management practices depends largely on the learning gained from the trials and errors of past practices:

The different management regimes being practiced today across various ownerships can be viewed as simultaneous experiments, but if the information required for analysis, comparison, and evaluation is not collected, and if one manager does not learn from another's mistakes, the capacity for learning through doing is substantially restricted.

Viewing information as proprietary, collecting and storing information in incompatible formats, and discounting qualitative data as unscientific, along with other institutional attitudes and behaviors, are barriers to open information flow.

The literature suggests that there is no straightforward, patterned approach to managing landscapes across multiple ownerships. Ostrum (1990) warned that attempts to "get institutions right" are not feasible if imposed from upper hierarchies, because there are simply too many cultural and conditional variables on any given landscape. Smith and others (1995) advocate nurturing informal authority across jurisdictions, where institutions that possess formal responsibility to manage resources participate in a supra-organizational forum to coordinate their plans and actions. These organizations may vary in both their degree of formality and their organizational cohesiveness.

At one end of the spectrum is a formalized advisory council with established rules and membership, and at the other end is a loose-knit coordinating body such as an ad hoc organization. Along this continuum of formality, participating organizations can determine appropriate levels of interchange and coordination. The following discussion addresses both the positive and negative aspects of the extremes of this spectrum, from the ad hoc strategy to the council strategies, and from the county context to the international context.

Ad Hoc Strategies—The least formal of the organizational forms to coordinate management across jurisdictions, ad hoc strategies tend to have highly fluid memberships. They begin small and are subject to changing priorities. Major strengths are their capabilities to be accessible to a wide spectrum of interests, to be relevant to local conditions, and to adjust to emerging interests. Their weaknesses are reliance on a few key players, who may become exhausted or disillusioned by slow progress; limited financial resources; and weak authority to ensure compliance of their recommendations among other formal organizations. The Applegate Partnership in southeastern Oregon is an example of an ad hoc organization that has participated in ecosystem management planning.

Council Strategies—Councils, or advisory councils, are generally formed through legislative or administrative initiative, and, unlike ad hoc organizations, often have a highly specific mission or task. Direct regulatory authority is not vested in a council, so their authority remains informal, but by virtue of their official sanction and the stature of their membership, their recommendations carry more weight than less formalized coordinating bodies (Lee 1993). The strength of councils is in their capacity to conduct analyses and the credibility associated with their recommendations. Councils generally operate with prescribed budgets to facilitate their ability to address complex issues common to cross-jurisdictional management. Councils are generally more cohesive and capable of reaching agreement on common goals than are less formalized groups (Agee and Johnson 1988). This latter strength is also the source of councils' greatest weakness; by focusing on membership of a particular type of individual or point of view, councils can exclude representatives who have creative or unsettling alternative solutions. Council agendas may, by omission, ignore key causal factors underlying problems in coordinated management, resulting in council recommendations that may be either too narrow or irrelevant. Additionally, in a more formalized structure, local residents who may be affected by a council's recommendations may feel excluded, possibly resulting in their opposition.

There are many examples of these types of institutions and many others, as discussed in this chapter about the public's role in ecosystem management.

Cross-jurisdictional approaches to ecosystem management require the BLM and FS to work not just with other federal entities, but with state and local governments to identify and accomplish mutual goals. A brief description of the structures and authorities within state and county governments in the Basin provides a vantage point for future research on institutional relationships for natural resource management.

States—Like agencies in the Federal Government, state agencies have divided legal jurisdictions over natural resource issues. Each state within the Basin has its own unique system of agency jurisdiction and policies that relate to natural resource management. Some state agencies oversee activities on public lands or share co-management responsibilities with the federal agencies. For example, the federal Clean Water Act requires the BLM and FS to comply with water quality management requirements of each state, and the agencies must also comply with substantive and procedural requirements of state and local agencies in managing air quality. In addition, co-management responsibilities exist because State fish and game agencies have responsibility for wildlife populations, whereas federal agencies manage much of the habitat.

To accomplish certain goals and mandates, the FS and BLM frequently enter into partnerships with state agencies. These partnerships allow resource management to be shared and combined to accomplish objectives beneficial to all cooperating partners. A state agency may become involved in cooperative arrangements with the FS or BLM when the state agency is interested in supporting a project through funding, labor, or supplies. Many of the relationships previously called cooperative efforts are now recognized as partnerships and documented with some form of agreement. Partnerships between the FS or BLM and state agencies can include memorandums of understanding (MOUs), challenge cost share (CCS) agreements, and collection agreements (Lee 1991).

Differences in priorities between state and federal agencies are expected due to the distinct mandates and constituencies of each. The FS and BLM are required to address the multiple demands placed on Federal lands under their management jurisdiction, whereas the state's fish, wildlife, and recreation agencies must address more specific objectives, often for a more specific population.

A common problem affecting government agencies in recent years is the difficulty in implementing complex mandates under conditions of continuing budget cutbacks. State agencies may possess the desire to assist in developing Federal policy, but have seen their responsibilities expand while their budgets are reduced. Budgetary constraints often restrict States from collaborating with federal agencies, even when requested to do so. Suggestions for greater efficiency to guide State and Federal interactions include improving coordination among federal agencies to facilitate communications and monitoring, using common databases between state and federal agencies (such as compatible GIS technologies), and reducing multiple reporting requirements.

Counties—County governments are a basic political unit of organization in the United States, providing services to residents within their borders and working in conjunction with the governments of states, municipalities, and other special districts to support the public's needs. The states, through legislative and executive mandates, play a large role in determining the services that counties provide, and also commonly use the county infrastructure to deliver the services (Davis and others 1992). County governments are far from homogeneous, reflecting tremendous differences in terms of physical, social, and financial conditions. For example, a 1992 report commissioned by the Oregon Association of Counties, entitled "County Services and Revenues in the State of Oregon", identified eight types of counties based on the location of Federal lands, diversity of economic structure, and population growth (Davis and others 1992).

The different management regimes being practiced today across various ownerships can be viewed as simultaneous experiments, but if the information required for analysis, comparison, and evaluation is not collected, and if one manager does not learn from another's mistakes, the capacity for learning through doing is substantially restricted.

Viewing information as proprietary, collecting and storing information in incompatible formats, and discounting qualitative data as unscientific, along with other institutional attitudes and behaviors, are barriers to open information flow.

The literature suggests that there is no straightforward, patterned approach to managing landscapes across multiple ownerships. Ostrum (1990) warned that attempts to "get institutions right" are not feasible if imposed from upper hierarchies, because there are simply too many cultural and conditional variables on any given landscape. Smith and others (1995) advocate nurturing informal authority across jurisdictions, where institutions that possess formal responsibility to manage resources participate in a supra-organizational forum to coordinate their plans and actions. These organizations may vary in both their degree of formality and their organizational cohesiveness.

At one end of the spectrum is a formalized advisory council with established rules and membership, and at the other end is a loose-knit coordinating body such as an ad hoc organization. Along this continuum of formality, participating organizations can determine appropriate levels of interchange and coordination. The following discussion addresses both the positive and negative aspects of the extremes of this spectrum, from the ad hoc strategy to the council strategies, and from the county context to the international context.

Ad Hoc Strategies—The least formal of the organizational forms to coordinate management across jurisdictions, ad hoc strategies tend to have highly fluid memberships. They begin small and are subject to changing priorities. Major strengths are their capabilities to be accessible to a wide spectrum of interests, to be relevant to local conditions, and to adjust to emerging interests. Their weaknesses are reliance on a few key players, who may become exhausted or disillusioned by slow progress; limited financial resources; and weak authority to ensure compliance of their recommendations among other formal organizations. The Applegate Partnership in southeastern Oregon is an example of an ad hoc organization that has participated in ecosystem management planning.

Council Strategies—Councils, or advisory councils, are generally formed through legislative or administrative initiative, and, unlike ad hoc organizations, often have a highly specific mission or task. Direct regulatory authority is not vested in a council, so their authority remains informal, but by virtue of their official sanction and the stature of their membership, their recommendations carry more weight than less formalized coordinating bodies (Lee 1993). The strength of councils is in their capacity to conduct analyses and the credibility associated with their recommendations. Councils generally operate with prescribed budgets to facilitate their ability to address complex issues common to cross-jurisdictional management. Councils are generally more cohesive and capable of reaching agreement on common goals than are less formalized groups (Agee and Johnson 1988). This latter strength is also the source of councils' greatest weakness; by focusing on membership of a particular type of individual or point of view, councils can exclude representatives who have creative or unsettling alternative solutions. Council agendas may, by omission, ignore key causal factors underlying problems in coordinated management, resulting in council recommendations that may be either too narrow or irrelevant. Additionally, in a more formalized structure, local residents who may be affected by a council's recommendations may feel excluded, possibly resulting in their opposition.

There are many examples of these types of institutions and many others, as discussed in this chapter about the public's role in ecosystem management.

Cross-jurisdictional approaches to ecosystem management require the BLM and FS to work not just with other federal entities, but with state and local governments to identify and accomplish mutual goals. A brief description of the structures and authorities within state and county governments in the Basin provides a vantage point for future research on institutional relationships for natural resource management.

States—Like agencies in the Federal Government, state agencies have divided legal jurisdictions over natural resource issues. Each state within the Basin has its own unique system of agency jurisdiction and policies that relate to natural resource management. Some state agencies oversee activities on public lands or share co-management responsibilities with the federal agencies. For example, the federal Clean Water Act requires the BLM and FS to comply with water quality management requirements of each state, and the agencies must also comply with substantive and procedural requirements of state and local agencies in managing air quality. In addition, co-management responsibilities exist because State fish and game agencies have responsibility for wildlife populations, whereas federal agencies manage much of the habitat.

To accomplish certain goals and mandates, the FS and BLM frequently enter into partnerships with state agencies. These partnerships allow resource management to be shared and combined to accomplish objectives beneficial to all cooperating partners. A state agency may become involved in cooperative arrangements with the FS or BLM when the state agency is interested in supporting a project through funding, labor, or supplies. Many of the relationships previously called cooperative efforts are now recognized as partnerships and documented with some form of agreement. Partnerships between the FS or BLM and state agencies can include memorandums of understanding (MOUs), challenge cost share (CCS) agreements, and collection agreements (Lee 1991).

Differences in priorities between state and federal agencies are expected due to the distinct mandates and constituencies of each. The FS and BLM are required to address the multiple demands placed on Federal lands under their management jurisdiction, whereas the state's fish, wildlife, and recreation agencies must address more specific objectives, often for a more specific population.

A common problem affecting government agencies in recent years is the difficulty in implementing complex mandates under conditions of continuing budget cutbacks. State agencies may possess the desire to assist in developing Federal policy, but have seen their responsibilities expand while their budgets are reduced. Budgetary constraints often restrict States from collaborating with federal agencies, even when requested to do so. Suggestions for greater efficiency to guide State and Federal interactions include improving coordination among federal agencies to facilitate communications and monitoring, using common databases between state and federal agencies (such as compatible GIS technologies), and reducing multiple reporting requirements.

Counties—County governments are a basic political unit of organization in the United States, providing services to residents within their borders and working in conjunction with the governments of states, municipalities, and other special districts to support the public's needs. The states, through legislative and executive mandates, play a large role in determining the services that counties provide, and also commonly use the county infrastructure to deliver the services (Davis and others 1992). County governments are far from homogeneous, reflecting tremendous differences in terms of physical, social, and financial conditions. For example, a 1992 report commissioned by the Oregon Association of Counties, entitled "County Services and Revenues in the State of Oregon", identified eight types of counties based on the location of Federal lands, diversity of economic structure, and population growth (Davis and others 1992).

Machlis and others (1994) termed counties important administrative units for regulations and policy in both the social and biophysical aspects of ecosystem management. County governments are becoming increasingly responsible for environmental management; a national survey of county executives found that environmental issues (including solid waste, land use and zoning, water supply/sewage, and toxic waste) are four of their top five concerns (Waugh and Hy 1988). McGown (1994) identified a large proportion of counties in Oregon, Washington, and Idaho that were involved in activities closely linked to ecosystem management such as planning, water quality monitoring, and wildfire mitigation.

Perhaps the most important aspect of the role of counties in ecosystem management relates to their responsibilities in land-use planning. County governments become de facto land management agencies addressing many ecosystem issues through zoning ordinances, property taxation collections, and comprehensive planning responsibilities (Machlis and others 1994).

Comprehensive plans for counties within the Basin indicate that county governments are taking a very active role in planning for future developments in land use, infrastructure, and economic activity within the Basin (Frewing-Runyon 1995). The counties anticipate having a major role in regulating development and identifying forest and agricultural lands to be protected from nonfarm and nonforest uses. Frewing-Runyon concluded her study by recognizing the important interactions that county-level planning may have with ecosystem management: "The importance of demonstrating knowledge and consideration of local desires for future conditions when making Federal land management decisions cannot be underestimated."

Important elements of cooperation among the FS, BLM, and county governments involve agreements for cooperative fire suppression, managed through regional incident command systems; search and rescue operations; public safety education; and other locally relevant, mutually beneficial services. On some occasions, the FS and BLM sign memoranda of understandings to document the scope and nature of their interactions. Even if rarely referenced, these documents establish a common interpretation of the expectations and responsibilities of each party. Although highly informal and not as yet considered to be official agreements as discussed earlier in this chapter, other kinds of cooperation remain fully relevant to more effective cross-jurisdictional management.

The significance of cooperative relations with county governments has been identified in various BLM and FS policy statements. The importance of agency relations to local and American Indian tribal governments propelled the 104th Congress to provide for a general exemption from the Federal Advisory Committee Act in Section 204 of the Unfunded Mandates Reform Act of 1995. The language within this Act instructed each Federal agency to "develop an effective process to permit elected officers of state, local, and tribal governments (or their designated employees with authority to act on their behalf) to provide meaningful and timely input in the development of regulatory proposals containing significant Federal intergovernmental mandates." This language removed a significant barrier to ongoing dialogue among these critical stakeholders.

Relations between county governments and the FS and BLM took on a new dimension in the Basin during the ICBEMP. The Association of Oregon Counties, the Washington Association of Counties, the Montana Association of Counties, and the Idaho Association of Counties created a new institution, the Eastside Ecosystem Coalition of Counties, to observe activities of the ICBEMP and to communicate the interests of county governments in the development of EISs associated with the project.

In spite of long-standing, generally favorable interactions between FS and BLM field personnel and local government officials, some counties are experiencing increasing polarization regarding the priorities for the use of Federal lands. Several counties in the Basin have adopted some style of

"county rule" ordinances to challenge the authority of Federal land management agencies. Rodriquez (1995) examined 12 Basin counties to observe any differences in economic and social characteristics that may help explain the presence or absence of ordinances and organized groups that oppose the actions of Federal land management agencies. Counties that were more rural and more likely to reflect an association with natural resource extraction were most likely to feel threatened by potential changes in Federal land management practices, and therefore, most likely to actively oppose Federal agency actions.

This trend generated new instructions from the Chief of the Forest Service regarding relationships with county governments (USDA 1995). Each field manager was directed to become personally acquainted with county boards of supervisors, attend their meetings, and brief them about Forest Service activities on at least a biannual basis. The comments of the Chief in the memorandum that provided these instructions offer an appropriate closing to this discussion:

> *We, collectively, need to enhance our relationships with the county governments within which counties our national forests lie. These folks are the elected representatives of a very important segment of our customers. And, more important, they are our neighbors. We belong to the same communities and share many of the same interests and responsibilities... This relationship is and has always been critical to achieving the Forest Service mission.*

International Context—An additional consideration is the international institutional context for ecosystem management. The FS and BLM, as part of a larger Federal Government system, are often connected to government-wide efforts to increase international coordination in the protection and maintenance of environmental quality.

The most widely recognized international event on environmental matters was the 1992 Earth Summit in Rio de Janeiro, Brazil, officially titled the United Nations Conference on Environment and Development (UNCED). Emerging from UNCED were several major international initiatives that involved years of negotiations: the Rio Declaration on Environment and Development containing 27 principles to integrate environmental protection and development; Agenda 21, a 40-chapter document to guide development into the 21st century; and the Forest Principles, a consensus on political will concerning management and conservation of forests.

Other types of nonbinding, bilateral (two-nation) and multilateral (more than two nations) agreements have been signed by representatives of the FS and BLM (or their superiors in the Departments of Agriculture and Interior) to promote coordination among nations on specific issues. These agreements include protocols on pest inspections in international shipments of wood products, cross-boundary fire suppression (with Mexico and Canada), and management objectives for migratory species such as neotropical migrant birds.

Of greater significance to the FS and BLM are public commitments made by the Clinton Administration to manage the forests of the United States in a sustainable manner by the year 2000. The meaning of this commitment was clarified in February 1995, with the signing of the Santiago Declaration by representatives of the U.S. State Department in Santiago, Chile. The Santiago Declaration is a nonbinding agreement among the nations in the temperate and boreal forest zones to identify criteria and indicators for the sustainable management of all types of forests. The declaration offers 7 major criteria and 67 indicators to measure progress toward this goal. The Forest Service has established a task force on sustainability to examine how agency behaviors are addressing these criteria and indicators.

Land and Property Rights

Land and the institution of property rights play a central role in ecosystem management. Along with labor and capital, land is a basic production factor. Being fixed in size and existing in the natural order of things, land is distinguished as a special and separate consideration (Marshal 1964). Land manifests a host of human values, from security, to work, to home. Land also anchors the decisions and actions of the BLM and FS and serves as the reference for agency missions, which allocate lands to various combinations of uses and benefits. As humankind developed agriculture and organized tribal groups, "land became a resource whose value was determined by the sacrifices in blood made in order to take or protect it. It is this development that changed expanse to land, formed society, and thus initiated the historical era of mankind" (Jacoby 1971).

Land possesses physical properties, including observable qualities such as location, size, and slope, as well as abstract properties such as the invisible bundle of obligations and relationships frequently described as property rights. Its physical properties provide one measure of land's capacities; if water is also considered part of the physical component of land, additional values are associated; and yet, the abstract properties of land attract our attention because they offer a much different picture of a land unit's potential.

The central issue in understanding property rights is the recognition that ownership is not the same as control. Others besides fee title holders possess interests and rights, and as society becomes increasingly complex and populated, constraints on land ownership increase. Many landowners maintain that property rights are absolute, even as more variable forms of ownership emerge (Lewis 1995) such as leases, development rights, community land trusts, or rights-of-way (Geisler 1993). Because property is an expression of multiple interests, new forms of property ownership will likely evolve as interests shift and new problems appear, suggesting that property is a social construct undergoing continual modification (Geisler 1993).

The idea of property shapes public expectations about the role of government, and the rapidly evolving private property movement presents important challenges for ecosystem management. The centerpiece of the current private property debate is the idea of "takings," based on the Fifth Amendment statement that "private property [shall not] be taken for public use without just compensation." Advocates for private property insist that government regulations, especially those initiated for environmental protection, constitute "taking" because they reduce the opportunity for property to be freely used at the discretion of the individual. Increasingly, policy decisions about "taking" are being made in the courts.

An additional land issue relating to ecosystem management is the effect of ownership distribution, which in turn determines public access to land and water resources. Due to an expanding population and a fixed land base, the value of private property has increased, constraining opportunities for land ownership by individual citizens. Public lands become the sole mechanism for many people to experience diverse types of natural resource opportunities. Even though one of the assumed pillars of a Jeffersonian-style democracy is a broadly distributed land-ownership pattern, land concentration nationwide among private owners has dramatically increased in the last century (Geisler 1993). In the West, the Federal Government manages much of the land, including a majority of the land in the Basin, and yet, ownership concentration among private landowners is also higher in the western states than anywhere else in the county. Trends are continuing toward further aggregation, as economic pressures in the 1980s forced consolidations in the farming and ranching sector.

Implications for Ecosystem Management

For ecosystem management to evolve as a strategy characterized by the principles outlined by Moote and others (1994), with adaptable institutions, holistic science, social identification of goals,

collaborative decision building, and operations on multiple scales, it must address a series of significant institutional challenges. Structural obstacles, such as the splintering of administrative jurisdictions among different governmental units, are but one type of barrier; legal challenges such as the Federal Advisory Committee Act (FACA) are another. An exploratory survey about challenges to implementation of ecosystem management was conducted by Schlager and Freimund (1994) with a sample of managers, practitioners, and natural resource scholars. Their study revealed a complex web of challenges (termed "barriers" in their report) that will require considerable attention before ecosystem management, as outlined in theory, may be realized.

The challenge most frequently cited by respondents to Schlager and Freimund's study was confusion surrounding the meaning of ecosystem management. Multiple definitions and interpretations have been circulated among administrative and academic circles, creating potential for the term to be so broad as to become meaningless. The term's ambiguity makes many members of the public think that the FS and BLM have ulterior motives. The term's ambiguity also creates unclear expectations, both by the public and many agency employees, who wonder if the status quo will continue, but with new names. A basis for these concerns is the language similarity used in defining broad goals under both multiple-use management and ecosystem management. The agencies hope that the documents being prepared as part of the ICBEMP will answer these questions.

A related challenge is that the direction for ecosystem management is a policy shift, rather than one based on new legislative direction. The management direction is not anchored in legislation that redirects multiple-use management into ecosystem management, and therefore does not reflect "a degree of political consensus" present in social objectives that have been codified in congressional legislation (Sedjo 1995). As a result, ecosystem management is being implemented under existing laws that do not necessarily contain consistent direction and cannot be viewed as reflecting a social agenda to proceed.

The Federal Advisory Committee Act, which imposes regulations on advisory committees to the executive branch of the Federal Government, was cited as another significant challenge to ecosystem management. Its regulations pertain to equal and open access, because FACA was enacted to protect against undue influence of industry groups to government decision-making structures. In other words, FACA was established to prevent abuses, not to encourage and facilitate balanced, representative public participation and the open exchange of ideas. Although FACA does not prohibit advisory committees, it imposes a set of regulations generally viewed as too restrictive for managers to meet independently for what is typically intended to be a less-formal (but still balanced and fair) process for seeking the knowledge and advice of stakeholders and the public. Managers within the agencies are very sensitive to violating FACA and being vulnerable to court challenges.

As mentioned earlier in this chapter, the Congress was aware of this barrier and exempted meetings between agency personnel and elected officials of state, local, and tribal governments (P.L. 104-4, Section 204). However, this provision does not address the issue of agencies collaborating directly with the public; FACA is especially nonsupportive of Federal participation in small-group, grassroots efforts to establish partnerships, working groups, task forces, or other forums for stakeholders to work together over time to reach a consensus and provide recommendations on public land management issues.

Another challenge identified was based on land and property rights. As discussed earlier in this chapter, ecosystems do not stop at boundaries based on land ownership. The ability of the FS and BLM to restore and manage ecosystems therefore will be limited, especially when private lands or the lands and projects managed by other agencies directly affect conditions on public lands. Ecosystem management conjures fears of increased direct or indirect Federal regulations on private landowners' management practices (Gray 1992, Lewis 1995, Sample 1992).

Ecosystem management has also been assumed to imply more strict application of environmental values (Cornter and Moote 1992), which private landowners suspect would create overbearing, costly planning bureaucracies.

Keiter (1994) proposes that the success of ecosystem management depends on the capability of agencies to demonstrate how such management would contribute to more stable economic opportunities for communities having traditional associations with resource extractions. With many of the small rural communities in the Basin undergoing transformations to new types of economic activity, many people are understandably anxious about the future. An expanded dialogue between public agencies and individual landowners about mutually desirable uses of natural resources appears warranted, particularly for the interests of society-at-large to find common ground among the interests of private landowners. Incentives for natural resource conservation or use may be incorporated into future expressions of ownership through models that have yet to be adequately explored.

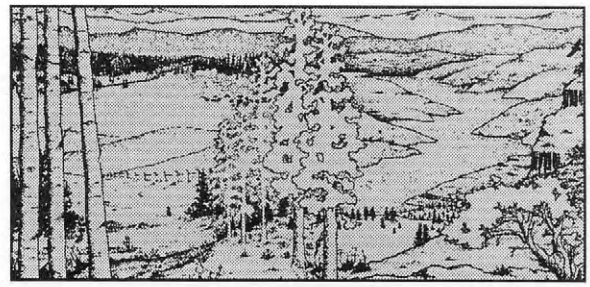
Schlager and Freimund also identified numerous agency policies and procedures that may need to be re-examined for their compatibility with the goals and principles of ecosystem management. The challenges to effective cross-jurisdictional coordination include the physical isolation of many FS and BLM field units, emphasis on decentralized decision-making, insular attitudes among staff about complex problems, and limited career payoffs for the considerable energy expended to achieve multi-agency coordination (Schlager and Freimund 1994). Other challenges are conflicting missions, values, and expectations among agencies (Agee and Johnson 1988), which may be further exacerbated by clashes between personal management styles and turf battles.

The disciplinary focus of natural resource professions tends to be restrictive, and only on rare occasions do specialists from diverse disciplines interact outside their own agency boundaries. Traditional training and reward systems encourage excelling at one's discipline, rather than collaborating and integrating with other disciplines. Compounding the situation is the inherent complexity and uncertainty associated with understanding ecosystems' functions: "The usual experience with ecosystem data is that there is not enough to define the biology with any confidence, but far too much for a single human mind to assimilate" (Lee 1993). This conflict also is apparent between social and natural sciences; there is the perception that ecosystem management is based solely on biological objectives (Sedjo 1995). Another identified challenge is the relative lack of agency employees trained in social sciences, communication and facilitation, and community planning.

One of the structural problems identified by Schlager and Freimund was the focus of agency activity around functional elements relative to budget appropriations. Hirt (1994), Yaffee (1994), and many other analysts have recognized this same functional emphasis, which translates operationally to the attainment of outputs; historically, the emphasis was simplified to "get the cut out." Attainment of these functional goals is a key factor in evaluating the performance of personnel, and rewards (promotions, recognition, prized assignments) have traditionally been based on meeting established targets (Boyle and others 1994).

An adaptive, ecosystem management approach would seem to be less captive to this type of functioned, output-oriented system, and as Shannon (1987) found, managers will be less responsive to innovation when rewards and a tolerance for experimentation are absent. The "holistic science" attribute of ecosystem management also encounters a structural challenge within the agencies by virtue of the organizational separation of research from management. Grumbine (1994) concluded that, "Implementing ecosystem management requires changes in the structure of land management agencies and the way they operate."

Revenues generated by timber harvests have historically funded a great share of management; more important, however, the commercial value of timber harvests supplied the purchaser credits to build roads on National Forest lands that provide recreation and wildfire suppression access. Timber



harvest revenues have been the source of deposits to the Forest Service's Knutson-Vandenburg and slash disposal trust funds, which provide monies for reforestation, sale area improvement, and fire hazard reduction. Broad interpretations on the use of these funds have provided countless improvements in wildlife habitat, riparian zone structure, and recreation developments. Timber, through providing revenue such as payments in lieu of taxes, is also the main source of funding that local governments have for roads and schools. Ecosystem management, however, emphasizes achieving desired ecosystem processes and functioning, not outputs such as timber volume.

The financial needs of ecosystem management, both in terms of planning and operations, may face a significant challenge without supplemental financing from other sources. A related concern is that adaptive management requires the ability to be responsive to monitoring results, which may be hampered by current legal requirements for plan modification and amendment. Research also plays a key role in ecosystem management, yet agency research budgets are being reduced substantially. Although monitoring assumes a particularly central role in adaptive management, there is typically inadequate funding for monitoring and also inadequate authority to make changes based on social or economic monitoring.

Administrative rules pertaining to contracting and bidding procedures affect delivery of benefits. Commonly, ecosystem management is linked to support of rural communities; however, the benefits associated with sales of commodities from FS- and BLM-administered lands do not necessarily accrue to individuals or enterprises sited in rural communities, because the commodities are auctioned under strict bidding and contracting rules. Aside from specific programs that provide small business set-asides, contracting rules let anyone participate in the purchase of Federal commodities. Although the logic of maintaining a fair and open process for purchasers is evident, the current contracting and bidding process may not be appropriate for ecosystem management specific to its intent to fulfill other objectives in support of rural communities.

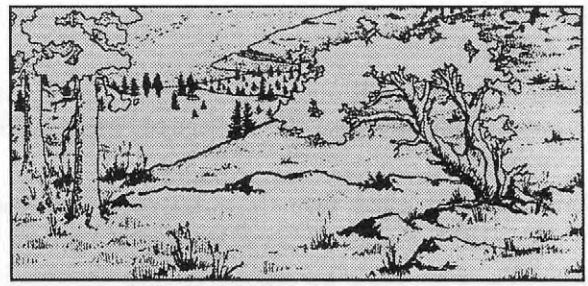
Ecosystem management could encourage experiments with variations of the sustained yield unit concept, along with monitoring of their socioeconomic and biophysical effects. For example, many entities have proposed stewardship contracts under which companies harvest timber and also undertake ecosystem restoration activities as an institution that appears compatible with ecosystem management goals.

In conclusion, a multitude of mechanisms are available to institutions to coordinate their land management operations. There is extensive potential to engage people in land management actions through planning, project implementation, monitoring, and evaluation. The issue facing natural resource management agencies in cross-jurisdictional management is more appropriately one of institutional will, rather than finding the "right" form for coordination. A flexible application of Federal programs offers greater potential for cross-jurisdictional management with state and other agencies, whereas relationships based strictly on rule applications inhibit cooperation and trust among the Federal and other levels of government. Based upon this social assessment, it is reasonable to expect that different types of institutions will be required for the philosophy of ecosystem management to be implemented effectively and efficiently.

ACKNOWLEDGMENTS

Numerous individuals contributed in a variety of ways to this document. To Roger Clark and George Stankey, we want to recognize the valuable contributions of your experience and advice in developing this assessment document, as well as the way we have interacted with the Science Integration Team. We want all readers to know that Steve Galliano and Gary Loeffler were valuable members of the Social Science staff and made major contributions to recreation, scenery, and concepts of place in this assessment and in individual background reports. Jon Bumstead played a role in implementing several of the contract reports initiated as part of this assessment. To our numerous contractors, we want to thank you for your outstanding help in advancing our understanding of the human component of ecosystem management.

The Science Integration Team provided the forum for testing ideas and the challenge for us to identify the stories that need to be told. We made individual acknowledgments within the text when we used a large share of material from one of the science reports.



Richard Hanes, Ralph Perkins, and Mary Keith helped us in compiling information on American Indians. Interactions with economists Richard Haynes and Nick Reyna contributed their insight. We want to thank Kathy Rose and Gary Machlis of the University of Idaho for their assistance in the social science symposium held in Spokane during April 1995 as part of our assessment. Many thanks also to Kathy Helm, Sylvia Arbelbide, Liz Galli-Noble, and Jodi Clifford for their editorial review.

We especially want all readers to know that our clients, the public, constantly provided us with the real world tests of relevancy and credibility. Our interactions with the public helped us to identify the nature of the stories needing to be told and challenged us to be sensitive to their needs.

BACKGROUND

Land use planning that is regional in scope and proportion requires tools more advanced than those typically used for landscape and resource analysis. Traditionally, maps, graphs, charts, and diagrams have been used to analyze and visualize the natural environment. These traditional methods of manually comparing hard-copy maps have limited accurate analyses to relatively small areas. Today, Geographic Information Systems (GISs) provide the tools and techniques that allow regional projects to be accomplished in a highly efficient, integrated, and accurate manner.

A GIS does much more than just make maps. It is "a computer-based system that provides the following four sets of capabilities to handle geo-referenced data: (1) input (data entry); (2) data management (storage and retrieval); (3) manipulation and analysis; and (4) and output (visual representation in the form of maps and charts)" (Aronoff 1993). These four items were important in the development and use of the large and robust database that supported the Interior Columbia Basin Ecosystem Management Project (ICBEMP). Without this advanced computer technology, software, and trained and experienced individuals, this volume of data would have been a great burden to the project. However, GIS allowed the Science Integration Team (SIT) to dynamically model and analyze living systems throughout the Basin in ways that were impractical only a decade ago.

A GIS is especially well suited for dealing with spatial and temporal problems (problems of dimension, space, and time). The number of kilometers of shoreline for a given lake is an example of a spatial problem that can be quite difficult to solve by traditional methods but is somewhat trivial for a GIS. More complex queries make a GIS a necessity. For instance, one might imagine the difficulty in a problem such as the following: locate, summarize, and display the number of hectares of major vegetation types, for all successional stages, on Federal, State, and private lands throughout the Basin. This example is typical of the GIS summaries performed for this project.

Any project that is both large in scope and under short timelines requires careful information and technology management planning. The ICBEMP is the largest interagency database development effort undertaken by the agencies involved, covering more than 58 million hectares (more than 144 million acres).

The ICBEMP information and technology plan was based, in part, on the plan developed for the Forest Ecosystem Management Assessment Team (FEMAT). Both projects involved many people but the team that developed the Northwest Forest Plan (USDA and USDI 1994a, 1994b) and the FEMAT assessment (FEMAT 1993) was centralized in one location and the timeframe was greatly compressed. The ICBEMP team had more time and considerably more data. Work for the ICBEMP

was accomplished in a number of locations in several states including Oregon, Washington, Idaho, and Montana. A dispersed approach to data collection and analysis was necessary due to the cost and inefficiency of moving all equipment and personnel to one location.

A Spatial Analysis Team was established to manage data and support the analytical needs of the ICBEMP. This interagency group was charged with the collection of available GIS data, capture of new data from prepared manuscripts, management of data, and data analysis in support of the SIT and Environmental Impact Statement (EIS) Teams. The Spatial Analysis Team was also responsible for the documentation and distribution of data to project personnel, federal agencies, tribal governments, the general public, and other interested parties.

This chapter is intended to provide a broad overview of the data, databases, and models employed by the ICBEMP and includes general recommendations for information management. Brief discussions of team organization, technology, GIS data and documentation, methods for integrating data, analysis methods, data release procedures, and data limitations are incorporated. A full discussion of the individual data layers and resulting analyses is not included. Much of this information can be found in either the documentation[1] for each GIS data layer or the various staff area chapters within this document. It is hoped that the documentation of the information resource methods employed by the ICBEMP and the recommendations resulting from them will aid future efforts and highlight the need for a long-term information resource management strategy as part of ecosystem management.

[1]The data layer documentation, or metadata, is available through the Interior Columbia Basin Ecosystem Management Project, 112 E. Poplar Street, Walla Walla, WA 99362, and on the internet (www.icbemp.gov).

Spatial Analysis Team Organization and Responsibilities

The Spatial Analysis Team consisted of BLM, FS, and contract personnel. Map 8.1 illustrates the overall distribution of the Spatial Analysis Team offices. Walla Walla and Portland were the core teams primarily responsible for overall data management and analysis. The other four teams provided data capture or specific analyses for the SIT.

The Spatial Analysis Team had seven task teams. They were: coordination and administration, information and product requirements, documentation and tracking, GIS operations, database design and analysis, quality control, and systems management. Most Spatial Analysis Team members served on more than one task team. Figure 8.1 outlines these task team group responsibilities. This organization allowed team members to understand their role and responsibilities better, and promoted external review of analytical products. The following sections briefly describe the major roles of the Spatial Analysis Team members in each location.

Walla Walla Organization

Spatial Analysis Team members residing in Walla Walla, Washington, provided local support to the SIT and EIS team. The Walla Walla office interacted with the SIT and EIS team to determine data and analysis needs; managed work priorities for the Walla Walla and Portland Spatial Analysis Team members; determined analysis requirements and procedures; interacted with the public and agency personnel; and coordinated all of the activities of the satellite offices using GIS. The Columbia River Basin SUccession Model (CRBSUM) and 6th-field-hydrologic-unit (subwatershed) data were stored and managed in Walla Walla. Most work requests for maps and analyses were also initiated in Walla Walla. The

Map 8.1— Spatial team organization.

Figure 8.1— Spatial analysis task-team responsibilities.

analysis of indicator variables for the ICBEMP science team and the EIS teams was completed by a database design and analysis group based in Walla Walla. This group created reports, spreadsheets, and graphics by producing numerous queries of the Columbia River Basin Landscape Assessment Database (CRBLAD).

Portland Organization

Two offices in Portland, Oregon supported the ICBEMP spatial analysis. The FS office (Region 6 Pacific Northwest Region) provided for data, system and telecommunication administration and tracking; work request processing; data capture; analysis of the current situation for the Assessment and the EISs; preparation of data for release; and GIS analysis technical oversight. Most of the Spatial Analysis Team members worked in Portland. The BLM (Oregon State Office) processed ICBEMP data released to the public and other agencies, and assisted in plotting map products for work requests.

Missoula Organization

In Missoula, Montana, two offices provided GIS support. The team at the FS Intermountain Fire Sciences Laboratory provided major support for the Landscape Ecology team members of the SIT. It prepared and documented the landscape data sets, processed data using the Vegetation Dynamics Development Tool (VDDT) and CRBSUM models for the assessment scenarios and EIS alternatives, and provided numerous analyses. The resulting scenario and alternative data "crosswalk" tables and maps were provided to the Walla Walla Team for further analysis. The team at the FS Region 1 office (Northern Region) provided hydrologic, riparian, and valley bottom setting data and analyses for the Landscape Ecology and Aquatic teams of the SIT.

Wenatchee Organization

The Wenatchee Team, which is at the FS Wenatchee Forestry Sciences Laboratory in Wenatchee, Washington, provided support for the Landscape Ecology Team's mid-scale analyses. The Wenatchee team organized the capture of subsample vegetation data, performed in-depth analysis of that data, and summarized the subsample data in a series of maps, reports, and graphs for the assessment.

Boise Organization

Two teams in Boise provided support for the Landscape Ecology Team of the SIT and the EIS teams. The team at the Boise National Forest Supervisor's Office (Region 4) provided for data capture of the subsample vegetation data. Once this work was completed, a subset of the team moved to the Upper Columbia River Basin (UCRB) EIS Team office to provide local GIS support including map preparation, database query, and an understanding of the assessment data. The team located at the FS Intermountain Forestry Sciences Laboratory provided the Aquatic Team with a variety of analyses and support.

Coeur d'Alene Organization

The Couer d'Alene Team located at the Idaho Panhandle National Forest Supervisor's Office in Coeur d'Alene, Idaho, provided support in the capture of the subsample vegetation and valley bottom setting data for the Landscape Ecology Team.

U.S. Geological Survey

The U.S. Geological Survey (USGS) Office of Mineral Resources, in Spokane, Washington, was responsible for earth science information. Mineral resource information was primarily focused on classifying land for its potential for undiscovered mineral resources and providing estimates of the size and value of those resources. It included diverse thematic maps that classified land by physical properties and potential for geologic hazards. The USGS developed GIS thematic data for and worked directly with the SIT on an ongoing basis.

U.S. Bureau of Mines

The U.S. Bureau of Mines (USBM) maintained extensive data on discovered mineral resources and past and present minerals development activities in their Minerals Availability System (MAS) Database. From this and other organizational sources USBM geologists, mining engineers, and mineral economists developed minerals themes illustrating mineral activity and its relationship to other resources. USBM scientists provided their expertise on a regular basis by working directly with the SIT on integrated analyses of mineral and biophysical themes.

Technology

An important advantage of a distributed GIS analysis model (GIS operations performed in many locations rather than one) was the ability of teams at separate sites to perform a wide variety of tasks simultaneously. While teams at Portland continued to capture important data, the Missoula team began to perform analyses and generate preliminary assessments and models. Geologists in Spokane could build maps showing mineral potential while scientists at Wenatchee assembled data for the mid-scale analyses. The main disadvantage of a distributed model was the difficulty in coordinating efforts and sharing data. These disadvantages occurred because moving all analysts and scientists to one location was not feasible.

Hardware and software

More than 100 computers, from powerful UNIX-based workstations to desktop personal computers (PAS), played a role in the work of the entire ICBEMP team. The major components for GIS tasks were IBM®, Sun®, and Data General (DG)® workstations (multi-user/multi-tasking computers), X-terminals (computers that provide access to the processing capabilities of the workstation), electrostatic and inkjet plotters, black-and-white and color printers, disk drives, Compact Disk-Read Only Memory (CD-ROM) drives, and tape drives.[2] Operating system software for these machines included various versions of UNIX (IBM, DG, Sun, Linux®, SCO®) and Microsoft (MS)-DOS®/Windows (Microsoft).

Various versions of GIS software contributed to spatial data collection, analysis, and map making. ARC/INFO® (Environmental Systems Research Institute, Inc.) played a dominant role. Both ARC/INFO® versions 6.1 and 7 were used because the length of the project spanned revision cycles of the software. Other spatial software included GRASS™ (Construction Engineering Research Labs, U.S. Army Corps of Engineers), ArcView2® (Environmental Systems Research Institute, Inc.), UTOOLS (Umatilla National Forest, Pendleton, Oregon), and LT4-X™ (Infotec Development, Inc). Major statistical software packages included S-PLUS™, Systat™, and SAS™. Analysts used Oracle™, Microsoft® Access© and Excel™, Borland Paradox®, and Quattro-Pro® to summarize and evaluate both non-spatial and spatial attribute data.

Telecommunications

Telecommunications played a key role in uniting the work and systems of the many project work sites. The Coeur d'Alene and Boise sites primarily conducted data collection. The site in Boise also provided end-user support for the UCRB team. Wenatchee and Missoula sites were involved in data collection and were also involved in analysis. Walla Walla served as the central hub where all data and analysis results were eventually assembled. Portland was the primary support site where the data were integrated, organized, and managed.

This telecommunication plan represented a distributed system of data and activity. A sophisticated telecommunications network was required to support such a system. Transfer of large data sets

[2] The use of trade or firm names in this publication is for reader information only, and is not an endorsement or recommendation by the U.S. Department of Agriculture, the U.S. Department of the Interior, the ICBEMP, or any of the affiliated agencies.

required rapid transfer speed and capacity exceeding typical communications lines and hardware. A typical residential telephone service could handle data communications for basics such as electronic mail and personal computer modems, but could not handle the volume of data transfer for this project. To meet the data transfer needs of this project, fractional T-1 and frame relay services were used. The service acquired was based on the projected data transfer needs of each site. Individual connections varied in capacity from 56 kilobits per second to 768 kilobits per second.

These telecommunication lines provided an infrastructure called a Wide Area Network (WAN), which supports work distributed among many sites. A WAN is a regional network. Sites at the end of a line are referred to as hubs. The node itself may be a single computer or a wide array of computers and communications devices. Any given site might also have many systems tied together by a Local Area Network (LAN). The Portland and Missoula sites had the most elaborate LANs due to the number of existing computer systems and the manner in which they were deployed. This allowed the PAS and UNIX-based workstations to communicate and share data.

Various protocols were used to enable computer communications between sites, including transmission control Internet protocol (TCP/IP), a computer communications protocol, telnet, a file transfer protocol (FTP), and network file system (NFS). All application protocols ran with TCP/IP. Telnet allowed authorized users to log into remote computers and execute applications such as ARC/INFO. For instance, a GIS analyst in Walla Walla performed analyses using a computer in Portland. FTP allowed a user to move files between computers, either locally (LAN) or regionally (WAN). NFS allowed a user to "mount" a device attached to another computer, such as a disk drive, and to operate it as if it were a local file system to the host computer. Although NFS has some convenient advantages, it can also put heavy loads on a network. Most data files were exchanged using FTP, while many programs were commonly accessed through NFS.

In addition, analysts and technical coordinators were all linked through commercial phone service and interoffice E-mail using the existing FS mail network.

GIS Data

A GIS allows for both simple and complex analyses in an attempt to measure and characterize real world systems and entities too complex to measure and understand by traditional hard-copy means. The nature of the problem to be solved or the desired end product helps determine the appropriate GIS model. The way the model is constructed dictates what analytical tools can be applied to it and how the results may be displayed. These spatial models are often referred to as spatial themes or data layers.

Multiple spatial themes of digital data in either vector or raster (cell-based) form comprise a GIS spatial database. A GIS is particularly suited for finding and measuring features within a single layer or among layers where different features occupy the same area on the face of the earth.

More than 170 different GIS data layers or themes were compiled or created in support of the ICBEMP assessment and the development of the Eastside and UCRB EISs. Table 8.1 lists the data themes and the scale at which they were collected for this assessment. Some of these themes have numerous files. The data layers were derived from source maps, photos, or transfer media ranging from 1:12,000 to 1:4,000,000 in scale. Some GIS layers mapped features continuously across the entire Basin, and others were for discrete areas only (for example, subsample areas). Map 8.2 illustrates the extents of the majority of the ICBEMP GIS data. Many landscape data layers were collected for an area larger than the assessment area (shown by the landscape characterization boundary in map 8.2) so that ecological units could be mapped in their entirety.

For naming convention and organization, the GIS data sets were named using a hierarchy of resolution, domain (geographic area extent) and theme group.

Table 8.1— Interior Columbia River Basin Ecosystem Management Project (ICBEMP) Geographic Information System (GIS) data.

Theme Name	Extent	Scale/Resolution
AQUATIC GROUP		
Benthic Invertebrates	Omernick regions 9-12, 15	variable

Theme Name Codes

(Sens): Sensitive data. Not releasable.

Extents

Assessment area: 'CRBA'. Assessment area of the Interior Columbia Basin Ecosystem Management Project. The area is comprised of Eastern OR and WA, most of ID, and parts of MT, UT, NV and WY.

Landscape Characterization Area: larger than the CRBA; includes more of ID, MT, UT,NV, WY & some of CA

Socio-Economic Assessment Area: also larger than the CRBA; follows county lines

List current as of 3/1/97.

Map 8.2— Major data extents for the Interior Columbia Basin Ecosystem Management Project.

A theme may consist of one or more data layers. Each layer may depict the same entity but have a different source or geographic extent. For this project, themes were organized into a more generalized category called a theme group. This system guided data storage protocols in the GIS corporate database in Portland. It also provided the foundation for organization of records in the Spatial Unified Data Dictionary (SPUDD) used to track and document each data layer. The following briefly describes the basic theme groups.

Aquatic

This theme group contained data relating to the aquatic environment such as stream inventory information and aquatic invertebrate and mollusk occurrence.

The stream inventory information was compiled from a variety of agencies and reformatted for use in the GIS. The aquatic species occurrence information was compiled from reports. This aquatic information was essential for describing and characterizing the historic and current aquatic communities.

Atmospheric

This theme group contained data sets relating to the physical characteristics of the atmosphere and included data such as air quality, precipitation, yearly temperature, average dew point, solar radiation, air pollution sources, and airsheds. Climatic information allowed analysts to classify and model biophysical environments.

Attributes

Numerous attribute files (tabular summary files that relate to GIS themes) have been developed in support of the ICBEMP. Information resulting from analysis, such as biophysical classifications watershed characterization, vegetation, and road density tabular data, have been summarized and related or linked to the subbasin or subwatershed GIS themes. These attribute files have played a key role in summarizing important biophysical and biological components of the Basin.

CRBSUM

This theme group contains Columbia River Basin Successional Model (CRBSUM) related data such as potential vegetation types, vegetation cover types, and vegetation structural stages. Most data in this group are input to or output from the model. The CRBSUM related themes were useful in characterizing the broad-scale vegetative conditions and disturbance patterns for the historical and current situation and predicted management futures.

Cultural

Data sets that describe features constructed or influenced by humans such as airports, railroads, dams, and roads, were included in the cultural theme group. These themes were derived from a variety of existing sources such as ArcUSA™, Digital Chart of the World (DCW)™, Census Bureau files (streets), and the United Parcel Service data set, or they were generated by the project as a result of analysis (predicted road density) or attribution of physiographic features (sense of place). The cultural themes were valuable to the Social, Economic, and other teams because they defined developed or socially valued areas within the project area.

Demographic

This theme group contained data sets describing the human population of the Basin by geographical units such as counties and towns (named places), or U.S. Census Bureau defined blockgroups, tracts, and places. Data consisted of demographic statistics from the 1990 U.S. census, and other social, economic, and lifestyle data. Census geographies and 1990 U.S. census information were extracted from Wessex Corporation "Profiler" and 1992 Census data sets. The census data provided information regarding population, gender balance, age, racial composition, employment, income, poverty level, and education level. Lifestyle information was contained in a data set purchased from Claritas Corporation. This data set provided

proportions of households within each census tract belonging to each of 62 lifestyle clusters. The clusters were determined by cluster analysis of standard demographic information plus a wealth of consumer behavior data. These demographic data sets were valuable tools that helped the social scientists describe the human population of the Basin.

Disturbance

Disturbance related information such a wildfire locations, historical and current fire regimes, and rural population/wildland interface fire risk areas are included in this theme group. This information was useful in describing historical and current landscape disturbances and areas at possible risk of disturbance.

Fish

Databases relating to fish and fish habitat were included in this theme group. The presence of key fish species for subwatersheds was determined using the fish distribution data systems acquired from each of the coordinating state agencies participating in the Northwest Environmental Database. The database includes the Oregon River Information System, the Washington River Information System, the Idaho River Information System and the Montana River Information System. Hatchery locations, diversions, and dams were also included in this theme group. Information describing the fisheries environment was essential in determining the historical and current status of key salmonids and other fish of interest within the Basin.

Hydrology

The hydrology theme group included delineations of the Columbia River basin, subbasins, watersheds, and subwatersheds across the area. Water bodies including rivers, lakes, and oceans captured at various scales were also in this theme group. Other data closely related to water features and various designated watersheds, such as key watersheds (FEMAT 1993), high priority watersheds and other watersheds, were in this group. Hydrologic information often provided the spatial foundation for our analysis work.

Minerals/Geology

This theme group contained all data sets relating to mining and mineral processing, mineral resources, mineral potential, or geology. All these data were provided by the USGS or the USBM. The mineral information was used to provide the locations of known or probable surface disturbing activities such as mine locations. The information provided a foundation for characterization of the physical properties of the Basin.

Physiographic

The physiographic group contained data sets describing the physical geography of the assessment area by characteristics such as landform, climate, elevation, and soils. There are data sets from previously compiled ecoregion and biophysical classifications including Bailey (1994) and Omernik (1987). Sources for the physiographic data sets included the Forest Service, The Nature Conservancy, and the Environmental Protection Agency (EPA). The physiographic data were crucial for characterizing and describing the biophysical environment within the Basin.

Political

Data containing features that were political designations or were human-created delineations were put in the political theme group. Examples include land management boundaries [such as the Northwest Forest Plan area (USDA and USDI 1994), ownership delineations, and management area classes], state and county boundaries, ICBEMP study areas, and both EIS boundary delineations. This information was used to describe the impact of current management and provided a means for summarizing information for all the SIT analyses.

Species

This theme group depicted the range of occurrence of terrestrial species such as birds, mammals, invertebrates, plants, reptiles, and amphibians within the Basin. This information was derived from expert knowledge, field guides, and other sources. The information was used for describing the known ranges of key species and probable suitable habitats within the Basin.

Terrestrial

Terrestrial themes described the flora or fauna within the assessment area. This group of themes contained information on known sensitive, listed, or candidate plant and animal species locations. This information was important for assisting in the determination of terrestrial species viability and population changes within the Basin.

Vegetation

Vegetative information collected included current vegetation, historical vegetation, potential natural vegetation, and life form. Vegetation information was collected at the broad scale (1 km) and for subsample areas at the mid scale (1:24,000). Current broad-scale vegetation cover and structure types were classified from the Advanced Very High Resolution Radiometer (AVHRR) satellite imagery (1 km) data set. Historic cover type and structure for the broad scale were compiled from numerous records such as early federal land survey descriptions. Potential vegetation types were determined by subdividing the Basin into warm/dry to cool/moist environments and associating the potential vegetation types and groups with these environments.

The subsample current and historical mid-scale vegetation information was derived from aerial photography interpretation completed by FS, BLM, and contract personnel. Cover type, structure, and other information was collected in this way.

The CRBSUM allowed for predictions of future vegetation cover types and structures across the Basin under different management scenarios. The vegetation information was crucial in describing and characterizing the current, historical and future conditions of the landscape within the Basin.

Methods for Integrating Data

For the ICBEMP, data sources (agencies) were selected for their expertise in a given field based on either local knowledge or experience in a discipline. The administering agency for a particular piece of land was considered to have the best knowledge about how the land was managed. An agency that specialized in a discipline was considered the preferred provider of data from that discipline. For example, geological data were acquired from the USGS, and fish distribution information was acquired from the Northwest Power Planning Council. Major data providers included individual administrative units of the FS, BLM, USFWS, EPA, USGS, USBM; the Bonneville Power Administration; universities; state agencies; and non-governmental organizations. A complete list of data providers can be found in table 8.2.

For a given piece of ground, mapping and classification of the environment varied widely between different scientists, organizations, and individuals. Some of this was a function of need and some was a function of differing interpretations, knowledge, and skills. These different mappings made the choice of data sources difficult. Data that were continuous across the project area were easier to deal with than data that had to be pieced together from a variety of sources. Some of the problems encountered when trying to compile a continuous data set from different sources included disagreement about features (spatial edge mapping), classifications, and attributes. The reason for using multiple sources was that the data were simply not available any other way, or the accuracy of the single source data was insufficient for the project's needs.

Table 8.2 —Major contributors of Geographic Information System (GIS) data.

American Fisheries Society-(AFS)	Oregon State University-(OSU)
Bonneville Power Administration-(BPA)	Sierra Biodiversity Institute-(SBI)
Bureau Of Indian Affairs-(BIA)	State Of California
Bureau Of Land Management-(BLM)	United Parcel Service-(UPS)
Central Washington University	United States Bureau of Census
Colville Tribe	United States Bureau of Mines-(USBM)
Environmental Systems Research Institute, Inc. -(ESRI)	United States Department of Defense-(DOD)
GAP Analysis Programs-OR, WA, ID, MT, UT, NV, WY	United States Environmental Protection Agency-(EPA)
Idaho Department of Fish and Game	United States Fish and Wildlife Service-(USFWS)
Idaho Department of Water Resources	United States Forest Service-(USFS)
Montana Fish and Wildlife-(MT-F&W)	United States Geological Service-(USGS)
National Park Service-(NPS)	University of Idaho
National Resource Conservation Service-(NRCS)	University of Montana
Nature Conservancy-OR, ID, MT, WY	University of Washington
Nez Perce Tribe	Washington Department of Natural Resources-(WA-DNR)
Northwest Power Planning Council-(NWPPC)	Washington Department of Wildlife-(WA-DWL)
Oregon Climate Service	Western Utility Group
Oregon Department of Fish and Wildlife-(ODFW)	Yakama Indian Nation
Oregon State Service Center For GIS (OSC)	

Although having accurate data was important, having continuous data across the project area was also necessary. To achieve this continuity while maintaining the best data source for a particular area, the following rule sets were applied when integrating data:

- In areas with conflict where one data set had higher accuracy than the other, the data from the higher accuracy data set were used;
- In areas with conflict where source data had equivalent accuracy, priority was given to the data from the federal agency;
- Otherwise, the analyst would consult the specialists in the subject matter and the determination as to which data had priority would be made.

It must be remembered that the resultant data set, without any more specific information on the origin of each piece of data, was only as accurate as the least accurate data set that went into its creation. Where data standards did not exist or were not followed, employing a lowest-common-denominator approach to ensure consistency was necessary. This meant that the data sets with finer attribute resolution would be reclassified into a coarser resolution.

In any case, data were inspected visually as well as through ancillary information. For example, paper maps, other GIS layers, and models using multiple GIS layers, were used to check for data anomalies and errors. The data with the most resolution were not necessarily the preferred data. The preferred data for the project were the data that met the analytical needs of the SIT, were continuous across the Basin, and were consistent.

Raster data had additional potential problems due to the rasterization process. The value at any particular point was determined by the underlying value that made up the majority of the individual cell. Where multiple attributes in a vector data set were reclassified into fewer attributes without due care, "logic" conflicts could occur. That is, the base data set might produce a different result depending upon whether the data were reclassified before or after rasterization. For example, if a given pixel (or cell) was 30 percent value A, 30 percent value B, and 40 percent value C, and the reclassification combined A and B to another class, the results would differ. The data that were rasterized first would have a value of C and not be reclassified, while the data that were reclassified first would have the reclassified value after rasterizing. As a rule, the data with the greatest resolution were rasterized and reclassification was done with that rasterized data set. See the Analysis section below for further discussions of the rasterization process.

Analysis

Analysis of data occurred in GIS and in the database environment. GIS analysis used two data architectures: vector (lines, polygons, and points) and raster (matrices or grids). Some data were created in vector form (such as information captured from a map, like ownership boundaries), while other data were created in raster form (including elevation models, vegetation models, and data based on satellite imagery). Vector data were sometimes converted to raster data for the analysis process.

GIS

Vector—Where all data required for analysis were in vector format, vector analyses were used unless they were too cumbersome. In that case, grid or raster processing was used to increase efficiency. Data quality information was used to assess the amount of precision that the resulting output would have. For example, an analysis using data from small-scale sources (such as a 1:1,000,000 source) would have less precision than an analysis using large-scale information captured from a 1:24,000 source.

Vector data sets were prepared to be as continuous as possible. When data sets were too complex or cumbersome, they were tiled or split into separate but identically structured pieces, based usually on states. In some cases an alternate tiling scheme, such as subbasins (4th field hydrologic units), was used. In either case, coincidence of lines between tiles was the goal, but due to the various sources and times of acquisition, and the amount of work required to achieve this, not all data were brought into strict coincidence.

Linear features, such as roads or streams, were more suited to analysis in vector format. The difficulty with linear features in a raster data set was that the minimum width of the feature became the width of the pixel (one unit of the raster). Additionally, where the feature was sinuous and nearly coincident with pixel edges, the width of the data feature sometimes assumed the width of two pixels. Also, networking and dynamically segmenting the data using the available software was easier in the vector form.

Raster—Examples of data captured in a raster format included topography, vegetation, climate, and the CRBSUM outputs. For consistency, most integrated analyses from which reports were made were done in raster format to simplify quality checking. Two resolutions were used: 100 square meters and 1,000 square meters (1 km^2 cells). The 100 square meter information was used when at least one of the following criteria was met: (1) the data were captured with sufficient resolution and accuracy to justify this resolution (in most cases this was from 1:24,000 sources), or (2) the data had relatively small polygons that were important to maintain. As the size of a data set's individual polygons decreased, the likelihood of missing a significant portion of the polygons during rasterization increased. Although there was no rule-of-thumb, the size limit was approximately two and one-half to four times larger than the cell size. It should not be assumed just because the

raster format had a resolution of 100 square meters that the data had the same accuracy. The finer resolution was used as a device to ensure that the overall values would be appropriate, without loss of data representation. The same argument can be made with the one-square-kilometer resolution data—a given square kilometer may not be very accurate, but when looked at in aggregate (with adjacent pixels), the accuracy increases.

As an example, the representation of lands administered by the U.S. Army Corps of Engineers (COE) in the State of Washington showed 398 hectares in vector form, 398 hectares when rasterized to a 100-square-meter cell size, but only 100 hectares when rasterized to a one-square-kilometer cell size. This occurred for a number of reasons. First, the variance of the difference increases with both increased cell size and decreased size of feature being represented. Second, COE ownership consisted of narrow scattered parcels of land, making it less likely that it would occupy the majority of a larger pixel.

Quality Assurance

With a GIS, there were a number of possible error types, including spatial, attribute, and logical. To minimize the number of errors a number of quality assurance steps were taken throughout the analysis process. However, limits on time and money prevented the team from ensuring that 100 percent of the errors were avoided. The team tried to keep the spatial and attribute features of the data as reliable as possible, as well as to ensure that no logic errors were introduced in the analysis or summarization routines.

Information gathered specifically for this project (that is, did not exist digitally before and was requested in a digital form to accomplish the objectives of the assessment) was either scanned or digitized once a manuscript of the data was created. These digital data sets were then attributed (features identified) and brought into the GIS. Further attribution, error checking, and analysis took place before the data set was placed into the corporate (master) data structure. These checks included manual inspection against other sources of data and logic checks both within the data set and with other GIS data sets. Errors, inconsistencies, and anomalies identified were resolved with the help of field specialists or other sources.

Data that were entered into the corporate data structure were plotted and inspected, and in cases of error or uncertainty, sent back to the originator for validation. Information about the data (metadata) that was compiled included information on scale and accuracy. This metadata were available to the teams and were included with any data distributed to other parties.

The output derived from the analysis required integration of many factors including differing requirements of the data by the SIT and differing qualities of the information itself (for example, differences in representative scale and data resolution). Comparing data from different scales causes the resultant resolution to be equal to the level of the most coarse data set. The scale of the data was difficult to keep in perspective. With over 58 million hectares of data coverage dealing with broad processes, the resolution of the data was more coarse than that with which most specialists were used to dealing. This difficulty was addressed by comparing pieces of the larger data set to pieces with which the resource specialists were more familiar.

To reduce logic errors, or errors in data use, a three-part system was implemented. First, communications between the requester and the geographic analyst were reiterated with great care. The request was written in a specific format and logged into the tracking database. The analysis was done with continued communication between the requesting team member and analysts. Second, routines used to accomplish these analyses were studied for logic. Third, the results were studied for anomalies. This was done by using a set of standard tables containing summary values for important, commonly used attributes derived at the different spatial scales and geographic extents. The different teams used varying areas

of analysis: the minimum area was the subsample subwatersheds scattered throughout the assessment area; and the maximum area was the landscape characterization area. The attributes of interest were pulled from the data and inspected against these summary tables for differences. Additionally, maps were made of the analysis results and visually examined by analysts and scientists to ensure they made sense, were consistent, and were accurate.

It must be remembered that these data were gathered, for the most part, across a large area, for a specific purpose. Much of the data was of poor quality when compared with data that would be collected for a site-specific project at the individual subwatershed level. The expense of gathering data of better quality (that met project level analysis requirements) for the entire Basin and aggregating it to the broad-scale level was too great to justify both in cost and time with the fixed amount of resources available. Some data were derived from broad general maps, while other data were captured through intensive, large-scale photo interpretation and high-resolution image processing. The importance of using and understanding the metadata to determine the appropriate use of GIS data cannot be overstated.

Inconsistencies and errors in the data sets are prone to propagation and repeated problems. Some data sets created at the onset of the project had slightly smaller extents than the assessment area. Other data sets may have non-coincident lines that represent the effect of a feature that causes attribute changes in both data sets. Such errors, if not corrected, introduce additional errors in resultant data sets.

In the analysis of the current, historical, and future scenarios, a variety of systems and methods were used to evaluate and analyze the mountains of existing and derived data. GIS played a key role in tying the CRBSUM outputs to the management regions, Ecological Reporting Units (ERUs), and subwatersheds. Conventional databases were essential to synthesizing, summarizing, and reporting information.

Databases

Columbia River Basin Landscape Assessment Database (CRBLAD)—The CRBLAD provided a common framework for relating data from a variety of sources. The database contains data tiled (organized) on 6th-field hydrologic units (subwatersheds) and was developed to summarize the major indicator variables for the assessment.

Using CRBLAD, a set of indicator variables was summarized by the Spatial Analysis Team for the historical (pre-European), current, and future management scenarios. This information was calculated from a combination of broad-scale vegetative and disturbance predictions from the CRBSUM and the ancillary information listed in table 8.3. Table 8.4 lists the indicator variables that were calculated with the database for use in the assessment. Many of these variables resulted from an assignment of a dominant condition to each subwatershed.

A database was used rather than a GIS to provide more efficient processing and generation of document-ready reports. Key spatial relationships were imbedded within the data using GIS software before it was transferred to a database. Input data sets were summarized to the individual subwatersheds using a GIS on a UNIX-based workstation and then transferred to a PC platform for integration into the CRBLAD.

The Access© development environment provided many features such as "querying by example" and broad import/export data formats that enabled the processing to succeed within a short timeframe. Data sets as large as 3.5 million records were encountered when processing; these required partitioning strategies. The total size of the final database was about 1.5 gigabytes.

Table 8.3— Subwatershed summary files used in the Columbia River Basin Landscape Assessment Database (CRBLAD). The following files were summary information from ICBEMP GIS data sets compiled by 6th field hydrologic units (subwatersheds). This information was used to determine the percent of each subwatershed in a variety of hydrologic, biophysical, political and cultural settings.

Subwatershed file	Subwatershed file description
H6Interp	Hydrologic summary file with watershed response characteristics such as: watershed sensitivity rating, erosion potential, sediment delivery potential and a variety of other hydrologic characteristics (see Chapter 2, Biophysical Environments).
Biochar	Series of files summarizing biophysical and related characteristics of subwatersheds such as: dominant landform, elevation, precipitation, climate, slope, ecoregion, subsection, potential vegetation, current vegetation, and historic vegetation.
Bioclass	Biophysical classification file assigning the dominant features to subwatersheds such as: landform, elevation range, slope class, bedrock geology, relief class, and precipitation class.
Curstat	Series of files summarizing current conditions within subwatersheds such as: surface ownership administration, administrative units (BLM/FS), management area classes (MACs), counties, grazing allotments, wilderness, predicted road density, life form, tribal ceded lands, tribal areas of interest, and minerals data.
Huc6lim2	Master 6th-field hydrologic units in project area and hectares of each.

A comprehensive analysis of probable data input and output requirements was done prior to creating the CRBLAD. This was a time-consuming process that led to the creation of both the high level data flow diagram of the database (fig. 8.2), and the object diagram showing the relationships between all data sources for the CRBLAD (fig. 8.3). This preplanning was an essential step in creating a database that would work as soon as it was created. The output of this analysis was also used to communicate data relationship issues to various work groups.

As data were transferred from the workstation to the PC-based CRBLAD they went through various formatting and quality control steps. These steps uncovered many potential and existing problems before any query and report activities were attempted. After the data were imported, relations to other tables were established at the database level to ensure referential integrity.

Once the data were entered into the system and passed the quality control procedures, they were combined to produce various output products. These products were generally hard-copy reports with corresponding spreadsheet and dBaseIV™ files. A summary subwatershed database (referred to as Executive Summary) was also produced for database analysis by other project users or for display using ArcView®.

Quality control of the output products was done by ensuring areas were summed to reference standards and by having a person other than the one producing the products visually compare them with previously generated reference documents. Primary documentation was done by recording design and processing activities as they occurred. After a set of output products was produced, database documentation software was used to print table, query, and report definitions.

Table 8.4—Indicator variables summarized by or predicted using the Columbia River Basin Landscape Assessment Database (CRBLAD).

REPORT NUMBER	VARIABLE NAME
LE-8B	Potential Vegetation Type
LE-9B	Vegetation Cover Type (wildland, urban, agriculture, other)
LE-10B	Vegetation Structural Stage
LE-11B	Vegetation Cover type/Structural Stage Combinations (terrestrial communities, and structure summaries by potential vegetation group)
LE-12B	Road Density Classes
LE-13B	General Disturbance summaries (prescribed fire, wildfire, harvest, insect and disease, and grazing)
AH-18B	Landscape Pattern Departure Index
LE-21B	Vegetation Pattern Classifications
LE-22B	Fire and Successional Regime and Fire Behavior
REC-2B	Estimated Recreation Opportunity Spectrum (ROS)
REC-3B	Scenic Integrity Classification
TERR-2B	Suitable habitats (for 20 vertebrates and 5 plants of interest)
AH-1	General Vegetation Summaries by Vegetation Code and Structure Stage
TERR-13B	Vegetation Summaries by Tribal Areas of Interest

CRBLAD was essential for providing a consistent analysis of the historical and current situation as well as future management scenarios for comparative purposes at the broad scale. CRBLAD and associated GIS data sets provided a context for major vegetative classifications, watershed effects, scenic quality, and disturbance regimes at the subwatershed level. Portions of the GIS data and associated databases may not be appropriate for project level analyses.

Other Databases—There were several databases developed to support the assessment. Table 8.5 outlines and briefly describes each of the major databases used for ICBEMP analysis. Most of these databases will be available to agency personnel and the public through the internal ICBEMP data release policy when they are adequately documented and finalized. Some of the databases can be spatially referenced to an existing ICBEMP GIS data layer. Detailed descriptions of some of these databases can be found in earlier chapters. Several databases were developed specifically for the project (such as the CRBLAD) and will have little utility for other projects.

Models

Several models were developed to simulate landscape changes, successional changes, recreational opportunities, and economic impacts of land management scenarios. The following briefly highlights a few of the major models developed for the ICBEMP. More detailed discussions can be found in the Landscape Dynamics chapter of this report.

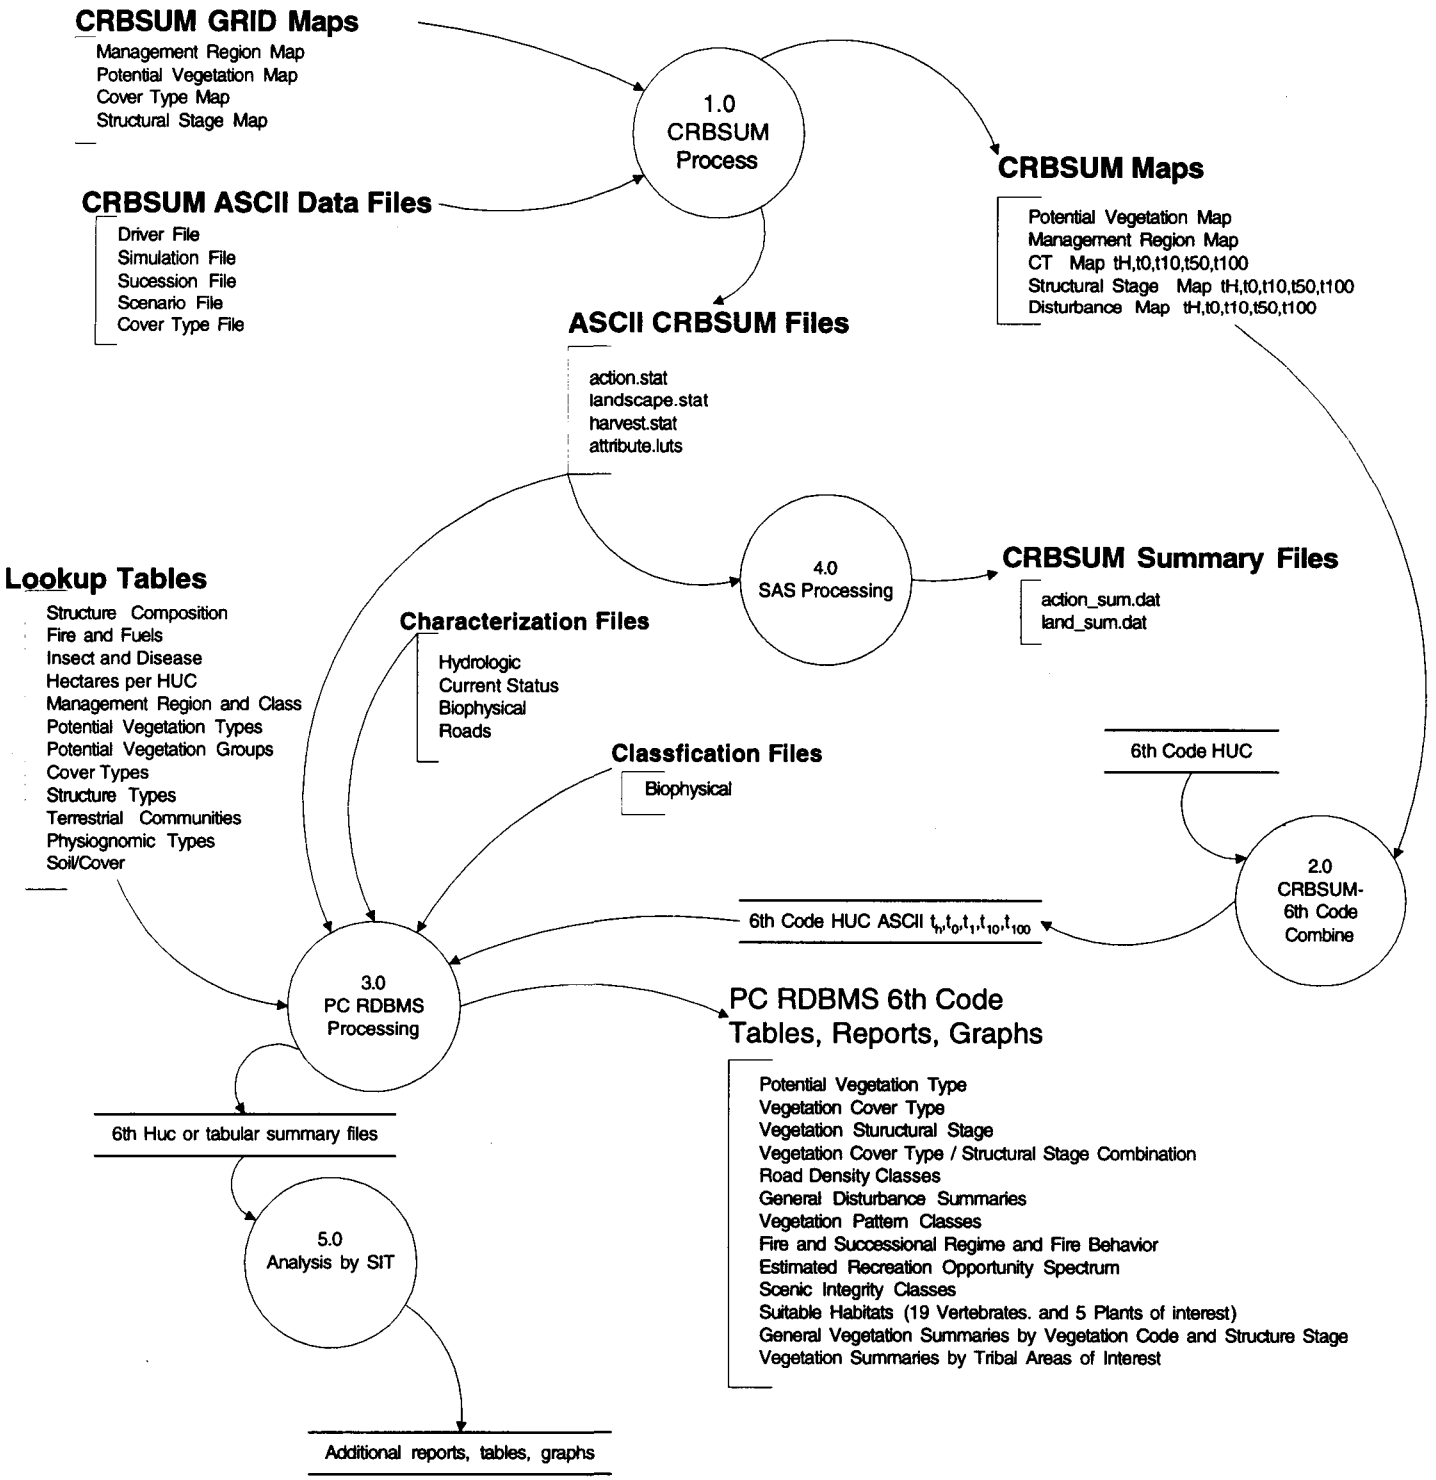

Figure 8.2— Data flow diagram for Columbia River Basin Landscape Assessment Database (CRBLAD). This diagram shows the flow of data for the Columbia River Basin Successional Model (CRBSUM) and Columbia River Basin Landscape Assessment Database (CRBLAD) portions of the Interior Columbia Basin Ecosystem Management Project (ICBEMP). The circles represent the major processes while the lists of text show the data that is passed either to or from a process. The numbers represent Process ID and do not represent process order. They are used for reference by more detailed process diagrams. In some cases the data lists represent groups of tables and/or files rather than a single entity. The input data on this diagram came from a variety of groups working on the ICBEMP.

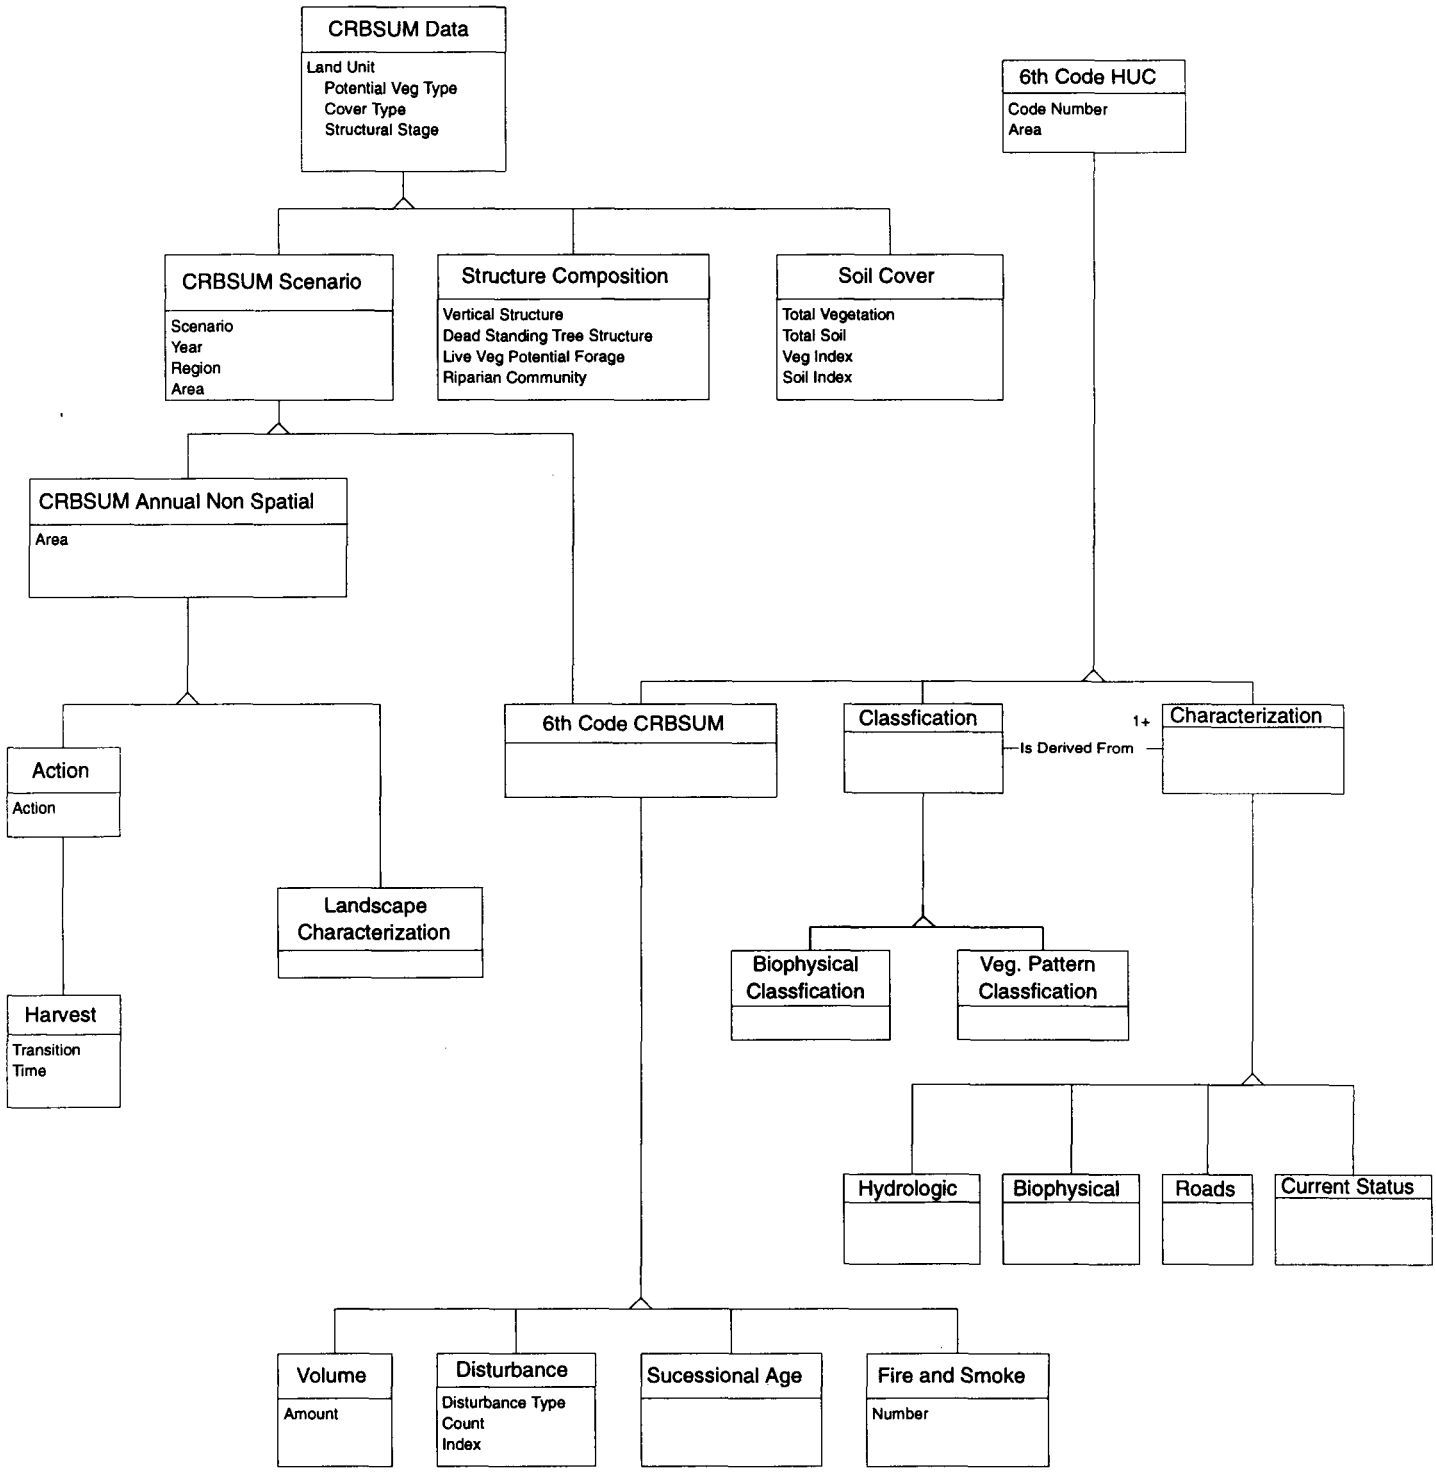

Figure 8.3— CRBSUM-6th Field HUC Input Object Attribute Inheritance Diagram. This diagram shows the attribute relationships between objects used to create the Columbia River Basin Landscape Assessment Database (CRBLAD). These attribute relationships are used to design database structures. The attribute relationships shown are hierarchial. The lower level objects inherit the attributes of the higher level objects.

Vegetation Dynamics Development Tool (VDDT)—The VDDT model was developed for the ICBEMP by ESSA Technologies Ltd. in Vancouver, British Columbia (Beukman and Kurtz 1995). This Microsoft Windows™ application is a user-friendly tool that allows for the non-spatial examination of the role of management activities and landscape disturbances such as fire, insects, and pathogens upon vegetation change. The interaction of these factors is often difficult to predict.

Pathways of disturbance types, their frequency, and the impact upon the vegetation were created for combinations of cover type and structural stages (referred to as "classes"). These pathways were used in the VDDT model to simulate vegetation dynamics over extended periods of time. Changes due to stand dynamics were determined by the amount of time a stand remained in a class and the successional class that it would become in time.

The VDDT model divided the landscape into pixels that were each assigned a successional class and age. The probability of each pixel being affected by a disturbance type was simulated non-spatially by the VDDT model. Pixels changed classes appropriately, independent of the state of neighboring pixels and disturbance history. The VDDT model did not simulate contagion (for example, cell-to-adjacent-cell probability) in space or time. Results were non-spatial and summarized by frequency distributions of cover types at different time intervals (years).

The most valuable aspect of the VDDT model was that it allowed scientists from varying disciplines to define the roles of disturbances and processes upon vegetation dynamics and readily display and review the results for a variety of management scenarios. The VDDT model will be released to agency personnel and the public in the near future.

Columbia River Basin Succession Model (CRBSUM)—The Columbia River Basin Succession Model (CRBSUM), created by the Intermountain Fire Sciences Laboratory in Missoula, Montana, spatially simulates broad-scale landscape level changes resulting from various land management scenarios. This model was used extensively in predicting vegetation cover type and structural stage changes for the management scenarios across the Basin.

Successional dynamics were modeled where community types or "classes" were linked along successional pathways to stable community types referred to as "potential vegetation types." Disturbances were stochastically (randomly) simulated as a change in successional class probabilities developed for each management scenario.

The Landscape Dynamics chapter describes the process of creating and rectifying the input layers for the CRBSUM. The model ran on a UNIX-based workstation. The outputs of the CRBSUM were summarized by a series of tabular files, maps, and GIS grids (raster data) by management region; vegetation cover type; vegetative structure; and disturbance type such as grazing, fire, harvest, and insect and disease (see Keane and others 1995). This information was summarized to the subwatersheds and fed into the CRBLAD for further processing. The CRBSUM results were found to have a 1 to 5 percent variability due to the stochastic nature of the model. These results served as the primary building block for the indicator variable analyses for the assessment.

The coarse-scale CRBSUM provided a useful tool for predicting and comparing vegetative trends resulting from a variety of land management scenarios.

Table 8.5— Databases and models obtained or created for the ICBEMP (as of March 1, 1997) [The following table provides summary information on databases and models created or obtained for support of the ICBEMP Assessment. Some of the databases listed below may actually be spreadsheets.]

Database/ model name	Description	Responsible team	Software	Platform	GIS data layer tied to database
Models					
Vegetation Dynamics Development Tool (VDDT)	PC based disturbance and successional pathway model that displays vegetative outputs (cover type and structural stage) for management options. Alternative and Scenario disturbances and pathways will be packaged and available.	Landscape	Windows	PC	None
CRB SUccessional Model (CRBSUM)	GIS model for predicting broad-scale vegetation management futures based on successional and disturbance pathways from the VDDT model.	Landscape	Unix, Loki and Arc/Info	Unix	Vegetation outputs from model (cover type and structure)
Wildfire and Prescribed Burn Models (CALMET/CALPUFF)	PC model for predicting emissions and visibility impacts of wildfire and prescribed fire.	EIS	dBase	PC	None
Aquatic Databases					
Columbia River Basin Stream Reach Information (CRBRID)	Stream inventory information linked to 17,000 km of river reaches within the CRB	Aquatic	dBase/ Paradox	PC	100K streams
Aquatic Integrity Measures	Measures of aquatic integrity by watershed (5th field HUC).	Aquatic	dBase/ Paradox	PC	None
Vegetation & Management Clusters	Classification of each subwatershed for dominant vegetative composition and management class.	Aquatic	dBase/ Paradox	PC	None

Table 8.5 (continued).

Database/ model name	Description	Responsible team	Software	Platform	GIS data layer tied to database
Fisheries Databases					
Key Salmonid Current Status	Classification of salmonid status within the 6th field hydrologic units	Aquatic	dBase/ Paradox	PC	6th field hydrologic units (subwatersheds)
Fish Species Assemblages	Species assemblages of native and introduced fish taxa	Aquatic	dBase/ Paradox	PC	5th field hydrologic units (watersheds)
Fish Subbasin Presence/Absence	Presumed historic distributions of sensitive, threatened, endangered, or special concern fish taxa	Aquatic	dBase/ Paradox	PC	4th field hydrologic units (subbasins)
Terrestrial Databases					
Endemism & Biodiversity	Documentation of the species comprising the centers of endemism and biodiversity that were delineated by the Scientific Panels	Terrestrial	dBase/ Paradox	PC	centers of endemism and rarity, centers of biodiversity
Species Environment Relations (SER)	Ecological function, environmental correlates and other information from Scientific Panels for candidate, threatened, endangered and sensitive plant, vertebrate, and invertebrate species	Terrestrial	dBase/ Paradox	PC	species ranges (for subset of species)
Landscape Databases					
Ecodata Plot Inventory (1940s-1994)	A synthesis of existing vegetation point data from numerous sources across the Basin.	Landscape	dBase/ Paradox	PC	None

Table 8.5 (continued).

Database/ model name	Description	Responsible team	Software	Platform	GIS data layer tied to database
Burgan & Hardy Fire and Fuels	Fire and fuels attributes derived for CRB vegetation.	Landscape	dBase/ Paradox	PC	CRBSUM historic or current vegetation data
Valley Bottom Settings	Valley bottom and stream type data summaries by each subsampled watershed.	Landscape	dBase/ Paradox	PC	Subsample valley bottom settings
Fine Scale Attribute Plot	Attributes derived from fine scale inventories using 0.10 acre ECODATA plot collection procedures.	Landscape	dBase/ Paradox	PC	None
Disturbance/ Vegetation	Predicted vegetation (terrestrial communities, physiognomic types) and disturbance (prescribed fire, wildfire, harvest, grazing) summaries from CRBSUM for management scenarios and EIS alternatives.	Landscape	dBase/ Paradox	PC	None
Other					
Demographic Databases Wessex Corp. "Profiler" and "Tiger 92"	Demographic information and statistics from the 1990 U.S. census	Social (purchased)	dBase	PC	census tracts and block groups
PRIZM Lifestyle	Data describing the proportions of households within each census tract belonging to 62 lifestyle clusters	Social (purchased)	dBase	PC	census tracts and block group

Table 8.5 (continued).

Database/ model name	Description	Responsible team	Software	Platform	GIS data layer tied to database
Columbia River Basin Landscape Assessment (CRBLAD)	Vegetative information and indicator variable classifications of 6th hydrologic unit codes for the historic, current and Scientific Assessment Scenarios. Created for analytical purposes only.	Spatial	ACCESS	PC	6th field hydrologic units (subwatersheds)
Columbia River Basin Landscape EIS Database (CRBLED)	Vegetative information and indicator variable classifications of 4th field hydrologic unit codes for the historic, current and modeled EIS alternatives. Created for analytical purposes only.	Spatial	ACCESS	PC	4th field hydrologic units (subbasins)
Alternative Summary	Vegetative information and indicator variable classifications of 4th field hydrologic units for various alternatives. Also includes integrity ratings for aquatic, hydrologic, forest and range.	Spatial	ArcView and dBase/ Paradox	PC/Unix	4th field hydrologic unit code (subbasins)
Noxious Weeds	Exotic plant species location by county	Landscape/ Terrestrial	Paradox	PC	vegetation cover type and structures
Community Self Assessment Workshop	Summary of information captured at ICBEMP Community Assessment Workshop.	Social	dBase	PC	none
Research, Development and Application (RDandA)	Research needs, data gaps and assumptions for staff areas	Landscape	Paradox	PC	none
Timber Mill Sites	Information about products and production of timber mills	Economics	dBase/ Paradox	PC	towns
Tracker	Administrative record tracking system	Administration	Paradox	PC	none

Documentation of Data

Metadata

In a project such as the ICBEMP, where many cooperators shared data obtained from many sources, documentation of data is a necessity, not a formality. The documentation of data, often referred to as metadata or data about data, is becoming standardized within the Federal Government. In 1994 Executive Order 12906 gave the Federal Geographic Data Committee (FGDC), currently chaired by the Secretary of Interior, direction to establish the National Spatial Data Infrastructure (NSDI) including the "technology, policies, standards and human resources necessary to acquire, process, store, distribute, and improve utilization of geospatial data." Part of that order calls for standardized documentation of data. Each agency must use the standard developed by the FGDC (FGDC Content Standard for Digital Geospatial Metadata) to document new data it collects or produces.

At the time initial planning began for the ICBEMP, the FGDC metadata standard was in early draft form and subject to change. The project adopted the metadata standard previously developed by the Northwest Forest Plan effort (USDA and USDI 1994a, 1994b). The resulting metadata are, in general, compatible but less extensive than those described in the 1994 FGDC standard.

For management of metadata, SPUDD (Spatial Unified Data Dictionary), an Oracle database application, was used. SPUDD was developed by FS and BLM personnel for use in the Northwest Forest Plan effort and was enhanced during this project. SPUDD has the capability to store information about proposed data sets, as well as documentation of existing ones. Table 8.6 lists the elements included in the metadata.

Automated Tracking Manager (ATM)

It was recognized at the outset of the ICBEMP that data tracking problems would result due to the large number of people involved at the various offices and to the scope of the analysis that was being planned. There was a desire to make data available to many people as soon as possible and yet to maintain control over the data so that the implications of data changes could be handled. The SPUDD was available to track metadata for themes as they became ready for use in the ICBEMP, but the SPUDD was not able to track the changes to the data after they were entered. For this reason the Automated Tracking Manager (ATM) was designed to track GIS data and associated metadata and recreate GIS processes if needed. Other commercially-available products were reviewed and found to be inadequate for project needs.

The ATM was built using ARC/INFO® and ArcTools© software. It is capable of tracking numerous types of ARC/INFO related data including coverages, grids, information tables, report files, graphic files, and automated macro language (aml) programs. When an existing file was tracked with the ATM it was considered a source file. Any file generated within the ATM was considered a derived file. All derived files in the ATM were created with amls that were also tracked with the ATM. This allowed the ATM to automatically recreate any files dependent on other files in the ATM if the source files were replaced or revised. The ATM contains several tools for evaluating the lineage of data and allows the user to understand the implications of revising data, not just on their own work but on all work done with that data. Because of the possible repercussions of changing data, the ATM was considered a master library for approved data and processes, rather than a development environment.

Table 8.6— Spatial Unified Data Dictionary (SPUDD) metadata definitions.

Identification Information: Describes the data's general content, main characteristics, origins and limitations.	
THEME NAME	Descriptive name indicating the thematic content of the spatial data set.
THEME ID	Unique number identifying this metadata entry.
THEME ABBREVIATION	The established abbreviation for the theme.
EXPORT FILENAME	A unique filename for use when the data are made available outside of the project.
PROJECT NAME	Name of the project or organizational unit for which the data set is being retained.
THEME DESCRIPTION	Description of the thematic content of the data set.
COVERAGE EXTENT	Describes the geographic extent of the thematic coverage for the specific file.
SOURCE	Identifies the organization providing the data.
LAST UPDATE	The date the source was captured or most recently updated.
FEATURE TYPE	The feature type of the data set (line, polygon, grid, etc.).
DISTRIBUTION LIMITATION	Identifies the nature of any limitation restricting sharing of the data.
THEME KEYWORDS	List of common words or abbreviations related to the theme.
DATA RESOLUTION	The dimension of the smallest resolvable object in the data set or description of a unit to which data were generalized.
PROJECTION	The name of the current projection of the data.
FILE PATHNAME	The pathname of the data set. Includes the disk location, directory and file name. If the file is located outside the project location, it can be retrieved from this location.
COMMENTS	Narrative giving information about data origins, characteristics, and limitations which has not been given elsewhere and which may be helpful to someone using the data. This could include when the data were first captures, by whom, for what purpose, and how they may have been subsequently modified. It could tell how complete the data are, give any literature citations, and describe concerns associated with the data.
Source Information: Describes documents used to compile the data.	
SOURCE SYSTEM/SOFTWARE	The GIS system and software name.
SOURCE SCALE	The scale of the source material.
SOURCE PROJECTION	The name of the projection of the source material.
CAPTURE METHOD	The way in which the source material was captured.

Table 8.6 (continued).

Custodian Information: Provides a point of contact for the data. "Steward" is the term used by the Forest Service in the Information Management Framework.	
CONTACT ORGANIZATION	The name of the organization acting as custodian of the data.
CONTACT PREFIX	The prefix of the contact person, if applicable (such as, Dr.).
CONTACT FIRST NAME	The first name of the individual to contact.
CONTACT LAST NAME	The last name of the individual to contact.
EMAIL	The electronic address of the contact.
CONTACT ADDRESS	The address to which correspondence may be sent for the contact. Includes 2 address lines, City, State, and Zip.
CONTACT PHONE	The telephone number of the contact person.
Processing Information: Describes the procedures and parameters used to convert the source materials to the final data and describes any derived layer/cover.	
THEME GENERATION PROCEDURES	Processing steps such as the execution of software commands, user-written programs, or other tasks that may affect the content and/or quality of the data prior to or during automation. If the processing steps include a transformation, then the type and error (root mean square error) should be reported. Also, this area may be used to describe any derived maps.
LINEAGE	A list of themes or files, by abbreviation or name, used to generate a theme.
DATA TRANSFER PROCEDURES	List the type of media being used for data transfer and any special instructions.
PROCEDURE CONTACT	The identity of an individual or organization responsible for the execution of any them generation or manipulation of any existing theme (technical contact).
Attribute Information: Describes the attributes associated with features portrayed in the data.	
LABEL TYPE	The identity of the software where the features are labeled. This may be a GIS or a relational database where attributes are linked to a spatial data set.
TABLE NAME	The name of the table where the attribute, or feature label, is located.
WIDTH (or POSITION)	The width (length) of the attribute, item, or field. This can also be used to give position/location when more than one value is encoded in a string.
ATTRIBUTE NAME	The identity, label, or name associated with an attribute of a feature.
ATTRIBUTE TYPE	Whether the attribute is binary, character, date, floating point, integer, numeric, or real.
ATTRIBUTE VALUE	The valid values of the attribute.
VALUE DESCRIPTION	The description or definition of each value.

The ATM relies on user input to determine location and lineage of data. The ATM requires the user to enter the following information about a data set: SPUDD theme, data location (directory/name), creator, date/time created, data type, lineage of data, amls used to create data and arguments given aml (if derived data). The ATM also generates more information when a derived file is created, such as the aml run time.

Functions in the ATM were organized into four major groups: data entry, data management, system administration, and reporting tools. The data entry tools facilitated the entry of source data, processing of amls, and running of amls to create derived data. The data management tools allowed for editing metadata, replacing data, deleting data, moving or copying data, and rerunning processes when derived files were older than their current source files. The system administration tools allowed user access control, scheduling of rerun batch processing, and easy access to ATM system tables. The reporting tools allowed the viewing and printing of any metadata and information on relationships between data.

The ATM provided a useful tool to determine how the GIS data sets related to each other. While most GIS work was not done within the ATM, it was used as a library of processes performed.

Graphics Tracking System (GTS)

The number of new maps and variations of maps being generated reached a point where the ATM was being overwhelmed with primarily plot generation information. A new, simplified tracking system, the GTS, was created to track just these graphic files. The GTS differs from the ATM in that it does not track any relationships between graphics, only the relationship between a graphic and the aml(s) used to create that graphic. The GTS is not actively tied to the Unix platforms where the graphics and amls reside.

The GTS was built using Microsoft Access software and is distributed using run-time versions of Access which access a central network database. It is organized into several modules including data entry and reporting.

The GTS relies on user input of information through Access forms, and requires the entry of the following information to define a unique record: file name, file location, title, coloration, plot size/scale. The GTS also allows entry of Subtitles, aml template, work directory, associated request number, and file size. It tracks and allows entry of amls independently of the graphics, but maintains user defined links between a graphic and the aml(s) used to create the graphic.

The Spatial Team work request database was eventually merged into the GTS system and is now available through the same interface.

Data Release

Data Release Policy and Process

The ICBEMP began to release spatial data and maps to the public and to government agencies in November 1994. Unlike previous projects, the data and maps were provided to the public and government agencies while the project data were being analyzed. A brief policy paper was prepared to provide interested individuals with the data release objectives, the processes for completing requests for data and maps, and cost information.

The ICBEMP has managed the release of data cooperatively with the BLM Oregon State Office from the time of the first release of spatial data and maps. The project office in Walla Walla received all requests for data, logged them, and sent them to the BLM Oregon State Office for processing. The BLM Oregon State Office contacted the requester with the actual cost (materials and time) to process the information and requested payment. The Public Room at the BLM Oregon State Office collected fees to release the information.

Updated Available Data Lists were prepared with each release of ICBEMP data. Data themes were not listed on the Available Data List until metadata were complete. Metadata and forms for ordering releasable data were available on the project's electronic library. On average, the project prepared a release of data every six weeks.

Sensitive data including threatened, endangered, and sensitive animal or plant species, archeological sites, or other resource data for which the release of locational information would be contrary to the agencies' statutory duties or regulations were not made available for public release. The ICBEMP did not release data layers obtained by the FS or BLM under a license or agreement restricting release.

Spatial information was generally released in ARC/INFO (an ASCII format) export format. Several formats were made available for the expected range of user applications in ARC/INFO and Map Overlay Statistical System (MOSS™). The requester was charged only for materials (tapes, disks, and paper) and time to download the files onto tape or disk. Metadata documentation and other descriptive information were provided to the requester along with the requested materials.

Memorandum of Understanding

Federal records, gathered for purposes of compiling an Administrative Record for the ICBEMP, formed the foundation for the decisions made by the FS and BLM. As such, the responsibility for these records was handled by the FS as outlined in a Memorandum of Understanding (MOU) between the two agencies. The MOU discusses the objectives, authority, procedures, records disposition, and administration for managing records generated by the ICBEMP.

Documentation of Data Limitations

Understanding the limitations of data created for use in the assessment is important. The following provides a brief description of these limitations and the process for creating several of the key coarse-scale data sets for the ICBEMP. Additional information can be found in the "Landscape Dynamics" chapter and the "Aquatic Species and Habitats" chapter in this document.

Management Region and Class—A GIS data theme was developed to represent Management Regions and Classes for use in the CRBSUM and in management scenarios. For the assessment the Management Regions were the Eastside EIS (EEIS) and the Upper Columbia River Basin EIS (UCRB) decision areas and Classes were groupings of ownership types. The BLM- and FS-administered lands were split into two categories: non-wilderness and wilderness-like. The Management Area Category (MAC) classification GIS data layer was used to create these categories. The MAC layer was generated for BLM- and FS-administered lands within the Basin in an effort to provide a basis for consistently displaying management direction on these lands and for use in assessing the overall affects on ecosystems. The criterion for mapping MACs was developed prior to the ICBEMP by Region 1 of the Forest Service and other cooperators. Table 8.7 describes the criteria for the eight MACs. The Management Classes used for each Management Region are shown in table 8.8. Further splitting of classes occurred in the EISs.

The Management Region and Class GIS data layer was rasterized to a 1,000 square meter (1 km^2) grid. A comparison of vector versus raster hectares of each Management Class across the Basin was very close. The rasterization process caused some long linear vector polygons to become generalized and counted in other classes. For instance, in areas within the assessment area where the ownership was scattered, the raster image was slightly more squared due to the pixel size of 1,000 square meters.

Probabilities for disturbance (grazing, fire, insects, harvest, and pathogens) were applied to the 12 management classes within the assessment area. The Management Region and Classes were also used to summarize the outputs of the CRBSUM and CRBLAD.

Table 8.7—Management Area Categories (MACs).

Purpose: Provide a basis for consistently displaying management direction of Federal (and other public) lands to use in assessing the overall affects on ecosystems.

Focus: Describe existing management direction to allow aggregation of similar areas to ecological conditions with an emphasis on human use and occupancy.

1. Natural, Unmodified Environments	Ecological processes such as fire, insects, and disease are essentially allowed to operate relatively free from influence from humans. Diversity resulting from natural succession and disturbance predominates and non-native vegetation is rare. Users must be self reliant and expect low levels of contacts with others. Few, if any structural improvement exists and travel is almost always nonmotorized. Typical types of areas: Designated Wilderness, Wilderness study areas, rivers designated/ suitable/eligible for wild river classification, most Research Natural Areas and back country lands.
2. Special Natural Areas	These areas provide for conservation of representative or particular rare and narrowly distributed ecological settings or components. This helps insure conservation of ecosystems or components that may provide important functions insuring overall sustainability of larger landscapes. The influences of humans on the ecosystem are sometimes evident. Types of human uses varies somewhat but generally is nonintensive. Travel is generally nonmotorized. Some of these areas help provide an important role under an adaptive management philosophy by providing a "natural" reference for areas heavily managed for particular objectives. These areas are often formally designated and include some Research Natural Areas, designated, suitable or eligible scenic rivers outside of wilderness, most (non-ONA) Areas of Critical Environmental Concern (ACECs), old growth reserves, and other special areas are typically included.
3. Essentially Unmodified Forested and Grassland Ecosystems	Although the areas are characterized by predominantly natural appearing landscape, an array of management tools can be used to restore or maintain relatively natural patterns of ecological processes. This will result in some evidence of man's activities. Ecological values are in balance with human occupancy with consideration given for both. Resource management activities may occur but natural ecological processes and resulting patterns will normally predominate. Users may expect to experience some challenge and risk. Restrictions on motorized travel can vary from area to area and season to season. This category would include all unsuitable forests and woodlands with no planned harvest, all special status species habitat areas and all designed and occupied wild horse/burro areas.
4. Natural Appearing, But Modified for Human Use and Occupancy	Ecological values are managed to provide human recreational use, but are maintained well within levels necessary to maintain overall ecological systems. Resource use for other values is not emphasized and has little impact on ecological structure, function, or composition. Human use is recreation oriented. Sights and sounds of humans on site can be expected and even desired. Motorized transportation is common. This category would include all designated/suitable/eligible recreational rivers, all non-linear recreation sites and areas, all other ONA/ACEC and environmental education sites.

Table 8.7 (continued).

5. Modified Forest Ecosystems	The areas are primarily forested ecosystems and are managed to meet variety of ecological and human needs. Ecological conditions will be maintained with an emphasis on selected structures and compositions within the range of natural variability. These lands often display high levels of forest management investment, use and/or activity, density of facilities; and evidence of vegetative manipulation activities. Forest users expect to see other humans and evidence of man's activities. Facilities in support of various resource use are common. Motorized transportation is common.
6. Modified Grassland	The areas are primarily grasslands, and many woodland ecosystems, and are managed to meet a variety of ecological and human needs. Ecological condition objectives are likely to have an emphasis on selected structures and compositions within the range of natural variability. These lands often display high levels of investment, use and/or activity, density of facilities, and evidence of vegetative manipulation activities. A wide variety of structure and composition is present. Users expect to see other humans and evidence of man's activities. Facilities in support of various resource uses are common. Motorized transportation is common.
7. Areas Modified by Human Occupation and Activities	Public lands are intermingled with private lands to the point that without the support and cooperation of the private sector, BLM/Forest Service cannot effectively manage for ecological values. Human activities have altered the natural appearances in most of these areas, both on private and public lands. Sights and sounds of humans are predominant. Private land use is often intensive agriculture, industrial or residential or zoned for residential (40 acres or less/lot). Resource use may not be planned on a sustainable basis but may occur in concert with surrounding private land values. Motorized transportation is common.
8. Modified Non-Sustainable Areas	Ecological conditions (including processes) are likely to be or have been permanently altered by human activities beyond the level needed to maintain natural appearing landscapes and ecological processes. The areas are generally small but could involve the core area of large mining districts. Ecological values are protected where they affect the heath and welfare of human occupancy. Areas such as mines and other concentrated uses are included. Human activities are generally commercial in nature and directly or indirectly, provide jobs and income. Motorized transportation is common.

Table 8.8— Management Region and Classes used for the Assessment.

Management Class	Description
FS/BLM Wilderness-like	MACs 1 and 2. Mostly wilderness, designated/suitable/eligible wild or scenic rivers, wilderness study areas, areas of critical environmental concern (ACEC), and research natural areas (RNAs).
FS/BLM Non-wilderness	MACs 3 through 8. All other BLM and FS lands.
Other Wilderness and National Parks	Wilderness on lands other than BLM or FS, and National Parks.
State and other federal lands	State lands and other federal lands: Department of Defense, Dept. of Agriculture Research Stations, U.S. Army Corps of Engineers, Department of Energy, Bureau of Reclamation, and US Fish and Wildlife lands.
Tribal lands	Tribal lands within reservation boundaries
Private and all other lands	Private land, county, municipal, and other lands

Edits were performed on some portions of the Management Region and Class grid to correct for missing data. During this process, a more generalized grid was inadvertently tracked as the new master grid. This error was not found until after the CRBSUM was processed for the management scenarios used in the assessment.

The overall impact of the incorrect grid was that the total hectares of BLM- and FS-administered lands were approximately 2 percent higher than the vector totals. Therefore, all reports from the CRBLAD for indicator variables had more hectares of land reported as administered by the BLM and FS. The error in the Management Region and Class layer was corrected for use in the EIS alternatives.

Coarse scale vegetation—The coarse (broad-scale) historical and current vegetation data were entered into the GIS at a 1,000 square meter (1 km^2) resolution. The current cover types were derived based on classified AVHRR data. Historical cover types were derived from a variety of historical cover type maps. Current structural stages were predicted using discriminant analysis (multivariable correlation analysis) based on the mid-scale subsample vegetation data [see Hessburg and others (1995) for more information on mid-scale vegetation sampling]. Historical structural stages were predicted randomly based on county records compiled within historical cover type units stratified by subsections.

The current coarse scale vegetation classification was based on the dominant cover type visible from the AVHRR data. Those areas that had the greatest reflectance within a pixel (cell) were the resulting classification.

Both broad-scale vegetation maps were a classification based on the best available data. Direct comparisons of current project level data (fine scale 1:24,000), cover type, and structure information for a particular piece of ground to the classified coarse-scale data should not be made.

Predicted road density classes—A continuous map or GIS data layer for existing roads and trails within the Basin was not available. There were several coarse scale sources obtained for the project including 1:100,000 USGS roads; a United Parcel Service road data set from Geographic Positioning

Systems (GPS); 1:2,000,000 roads from ArcUsa®; 1:1,000,000 roads from the ESRI Digital Chart of the World (DCW); and 1:100,000 roads compiled from a combination of Census Bureau road files. All these existing data sets were continuous across the Basin but were missing most of the unimproved roads and those built by the BLM and FS for logging and other purposes. To analyze the impacts of road disturbances upon terrestrial species migrations and aquatic environments, more detailed information was needed.

The ICBEMP collected more detailed road information in the subsample subwatersheds across the Basin (see "Landscape Dynamics" chapter for a description of the subsample effort). The BLM and FS mapped roads within each subsample and noted a variety of attributes, such as road closures and road surface type, using orthophotos and aerial photography. This information was entered into the GIS. It was a fairly accurate indicator of the road density within the individual subsamples.

From the combination of these data and other information such as ownership, other road data sets, digital elevation models, and MACs, a predicted road density class 1,000 square meter (1 km^2) grid was created using a statistical rule-set (see "Landscape Dynamics" chapter for additional information on this process).

Each 1,000 square meter pixel was classified into one of the following road density classes:

None	(0 - 0.02 mile/square mile of roads)
Very Low	(0.02 - 0.1 mile/square mile of roads)
Low	(0.1 - 0.7 miles/square mile of roads)
Moderate	(0.7 - 1.7 miles/square mile of roads)
High	(1.7 - 4.7 miles/square mile of roads)
Extremely High	(4.7 or more miles/square mile of roads)

From this 1,000 square meter grid a 6th-field hydrologic unit (subwatershed) GIS theme was developed using a weighted average based on road density class midpoints. This data set was used for subwatershed characterization and analysis in GIS and other databases. The subwatershed predicted road density GIS layer was used in the CRBLAD as the baseline for current road densities. For each of the management scenarios for the assessment, road densities were predicted for each subwatershed based on a rule set.

In general, the statistical extrapolation rule set for the 1,000-square-meter road density grid was conservative toward higher road densities. Since the road density classes increased in width and size of midpoint, the weighted average for the subwatershed version also tended to be conservative toward higher densities. In many areas of the Basin where there were narrow mountain ranges, areas that should have been roadless (such as the Cabinet Mountain Wilderness Area in Montana) were shown as roaded in the subwatershed road density classification. Subwatersheds at each side of the narrow mountain range had roads in the lower end of the subwatersheds and these roads were averaged into the total subwatershed.

The Aquatic Staff conducted a ground truthing of the subwatershed-predicted road density layer within several 4th-field hydrologic units on the Umatilla National Forest, Wenatchee National Forest, Ochoco National Forest, and the South Fork Salmon River area of the Payette National Forest. The subwatershed predicted road density classes from the project were compared with actual National Forest level data for 155 5th-field hydrologic units. Accuracy of the subwatershed predictions was as follows: Umatilla and Ochoco National Forests were 86 percent, Salmon River was 44 percent, and Wenatchee Forest was 71 percent. The more detailed results of this comparison are in table 8.9. The possible reason for lower accuracy on the South Fork area could be the higher variability of road densities in Management Area Categories 3 through 8 (non-wilderness areas). This appears to be typical of most of the UCRB EIS area.

Table 8.9—Summary of the comparison of the Interior Columbia Basin Ecosystem Management Project (ICBEMP) predicted subwatershed road density classes to actual forest road density data.

Comparison of Actual Forest Road Density Class to ICBEMP Predicted Road Density Classes	Number of 5th Field Hydrologic Units and Percentage		
	Umatilla/ Ochoco Forest	**Salmon Forest**	**Wenatchee Forest**
Same	48 (86%)	25 (44%)	30 (71%)
Higher	6 (10%)	10 (17%)	7 (17%)
Lower	2 (4%)	22 (39%)	5 (12%)
TOTAL	56	57	42

Overall the 1,000-square-meter predicted-road-density layer can be rated as a good estimate of the actual road situation in the Basin, given that it was based on a 3 percent sample of subwatersheds and a fairly conservative rule set. The subwatershed GIS data set can be rated as a fair estimate of the current road situation, given the conservative nature of the rule set and the averaging of mid-points from unequal classes. A road density class rating could be highly skewed in individual subwatersheds; that is, the roads could all be in one part of the subwatershed, and the rest could be roadless. Given that subwatersheds range in size from 200 hectares to 10,000 hectares, this could result in a significant misconception if the limitations are not considered.

The predicted road density GIS layers created for the ICBEMP were a classification that was valuable for estimating broadscale disturbance impacts such as sediment transport and erosion within the assessment area. These classifications were not meant to be a replacement for a mid- or fine-scale continuous road layer. It is important to remember the limitations of these data sets. They should be used for relative comparisons only.

Research, Development, and Application Needs for Information Management

A key element for ecosystem management is the need for consistent, current, and accurate information concerning the ecological and biophysical environments across the landscape. This information is necessary at several levels of resolution. Research is needed to develop better data structures that link scales (both temporal and spatial). To implement ecosystem management, the collection and management of these data, and information between Federal, state, and local agencies need to be effectively coordinated and shared. Federal, state, and local governments working with the public can help ensure success through a shared commitment and vision.

Inventory and Monitoring Needs

An ongoing commitment to ecosystem management and modeling will mean that federal agencies will need to reassess their individual resource inventory programs and strive for a set of interagency standards tied to ecosystem management. Currently, data are collected in many formats both between and within agencies. This makes inte-

grating data very difficult. Data need to be collected for all ownerships across ecosystems in a standardized fashion for ecological and biophysical information. Minimum data standards for vegetation, aquatic, fisheries, and terrestrial components of the landscape need to be established. Additional information in excess of the minimum required could be collected by individual agencies for their own needs. Data collected at the project level, once standardized, could be aggregated for mid-scale and broad-scale analyses.

Maintenance of ICBEMP Data and Models

The GIS data and associated databases collected and created for use in the assessment need to be managed, maintained and shared. A central information clearinghouse could be established to support the update and implementation of FS and BLM plans. This clearinghouse could manage, distribute, and provide user support for both spatial and non-spatial data and models from the ICBEMP. Agencies could profit from the information investment of this assessment by developing processes for long-term resource information management that benefit ecosystem management.

There are several GIS data layers that need to be standardized and collected continuously across the Basin for broad-scale and mid-scale analyses. Many of these themes have been created or collected by the ICBEMP and may be used for project level work where no finer resolution data exist. There are some additional data that will be needed for implementation of ecosystem management principles.

Standardization of Existing Data

Standardization of theme content and attributes for the following data sets would assist in building a more functional interagency data set for future work. Such an interagency data set could be built once the following building blocks were put in place:

- Administrative boundaries
- Surface ownership administration
- Current land use allocations for all agencies
- Natural areas, wilderness, and unroaded areas
- Current Management Area Categories (MACs) for all agencies.

Maintenance of Priority ICBEMP Data

Many of the newly captured data sets from the ICBEMP could be maintained and improved for future analyses including implementation of plans, watershed analyses and project level planning. Major effort and expense went into the continuous and consistent entry (data capture) of many of the GIS data layers and associated databases across the assessment area. These include but are not limited to:

- 6th-field hydrologic units (subwatersheds)
- Broadscale vegetation (1 km^2)
- River reach stream inventory and databases
- "Fish Related Databases".

Data Needed for Implementation of Ecosystem Management

A number of critical data sets needed by ICBEMP were not readily available across the assessment area nor could they be captured into GIS in time for use by the project. For use in project level planning and implementation of Forest and BLM plans, the following GIS data sets are important to standardize and capture continuously across the Basin:

- Land type associations;
- Consistently classified vegetation from satellite imagery (mid-scale vegetation);
- Enhanced 1:100,000 stream network (until continuous 1:24,000 base data is available);

- Base data at 1:24,000 [digital elevation models, cultural features, streams (should be enhanced), and roads (enhanced to contain logging roads and others not on USGS base maps)].

Enhancement of Existing Models and Databases

A few of the existing models, such as the VDDT, have been fully documented and have user guides, while other models, such as CRBSUM, have limited documentation and need additional work before they can be released to FS and BLM offices. The following are examples of some of the types of enhancements needed to make the existing models and databases created for the ICBEMP more useful for the future.

- To the extent possible, make critical models and databases more user-friendly, with pull down menus, user interfaces, and user guides.
- Develop CRBSUM to run at the mid-scale level with the contagion function for use with field office vegetation data.
- Enhance CRBSUM so that novice users could run it efficiently.
- Provide training on use of models and key databases developed for the ICBEMP.

Technology Transfer

A technology transfer program would provide field offices, other agencies, and the general public with access to and comprehension of the data, models, and information that were developed for the ICBEMP. Technology transfer is crucial for providing user support and training to the field offices over the next several years. Maintenance and periodic update of the GIS data, databases, and models collected and developed for this project will benefit subsequent regional analyses. Otherwise, the data will become outdated. Refer to other chapters in this document for additional research, development, and application needs for implementing ecosystem management within the project area.

Major Information Issues and Recommendations

The information and technology plan developed for the ICBEMP was functional and fairly efficient for a project of this scope. The overall project was larger than was actually planned in terms of the number of people involved, the amount of data collected, and the scope of analyses performed. In addition, the project's timeline was overly ambitious for what could actually be accomplished for many of the tasks. Several things could be improved in future projects of this type.

Data Development, Documentation, and Analysis

Many of the GIS data sets took over nine months to compile or create. Time could have been spent more efficiently if key base data, such as subwatersheds and broad-scale vegetation (1 km^2), had been available at the beginning of the project. Many GIS themes that should have been based on subwatersheds were created before the subwatershed layer was finalized. This required data to be modified once the subwatershed layer was available. A stepwise approach should have been followed for completion of many of the base biophysical layers.

Data were received from many organizations, agencies, and individuals. The Spatial Analysis Team collected metadata for each layer from the provider. Although this process worked well, metadata should have been reviewed, edited, and verified against the actual GIS data layers early in the project. Much time was spent correcting inaccurate information or gathering more information from the data source.

A formal quality control process for analysis and data layers was in place in Walla Walla and Portland. Both the GIS analyst and the appropriate SIT member reviewed GIS data layers before they were used for analyses. However, in several instances, data from the individual National Forests or BLM Districts were missing, an oversight that

required re-processing of data and analyses. During projects with tight timelines quality review of information is often difficult because individuals are simultaneously performing a variety of high priority tasks.

Standard map templates were developed and shared between analysis sites for large size plots (1:1,000,000 and 1:2,000,000) early in the project. Page size map templates that ensured that all maps were the same extent and could be overlayed were not developed until later in the project. Such a standarized template would have ensured that all products were similar and could be used together.

The ICBEMP data release process was very successful. By having a specialized group (Oregon State Office of the BLM) handle and process data release, analysts were able to concentrate on GIS analysis. Metadata nad other project information are available on the ICBEMP home page (www.icbemp.gov). The release and distribution of data via the Internet did not materialize until the latter part of the project. This slowed interagency connections at the Federal level, coordination with other agencies and organizations (data collection and distribution), problem solving, and information sharing. Using the World Wide Web/ anonymous FTP to distribute data and share information with agencies and organizations with Internet connections will be an effective information sharing route. This distribution route is currently being developed and ICBEMP data are expected to be made available in the summer of 1997.

Much of the data and analyses for the ICBEMP had not been developed before, and the creation of a formal information needs assessment plan was not possible at the onset of the project. This would have been helpful in managing the project since many of the SIT members could not, initially, determine their analysis needs for a project of this scope, and since more data and analyses were continually added throughout the project. Most SIT staff areas relied heavily on the Landscape Ecology Team to determine the broad-scale analysis procedures since they were most familiar with the biophysical data and broad-scale processes. This caused a bottleneck during the analysis phase. Broadscale analyses of this type and scope had not been performed prior to the ICBEMP and many procedures had to be developed during the analysis process. A limited set of models was tested during prototyping. However, all procedures and analyses could not be tested due to time limitations. If they had been tested, the overall analysis process might have run more smoothly.

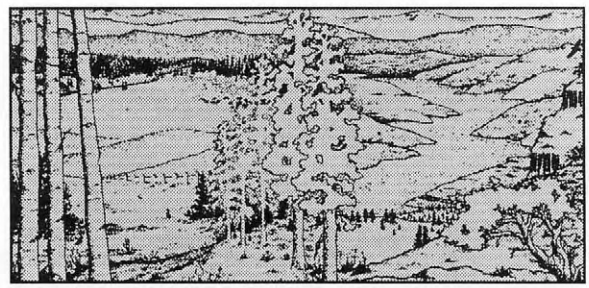
Distributed Work Sites and Systems

The telecommunications network between the distributed analysis sites allowed resources (human and machine), which would not have been available otherwise, to be accessed for the ICBEMP. It would have been difficult to physically move some of these resources as they were also dedicated for other activities and duties outside the ICBEMP. Additionally, costs of relocating personnel and equipment were reduced. However, the lack of face-to-face communication hindered understanding of both data and analysis needs. It also took more time to solve problems and answer questions concerning analysis requests between the various offices. All GIS processing and data development would have been more efficient if the analysts and scientists had been in one location. To improve interagency coordination in the future other federal agencies could be added to the WAN that was established for the ICBEMP.

The Portland and Walla Walla offices dedicated certain individuals to perform certain tasks such as preparing plots, documenting metadata and data release, performing quality control, or serving as primary analysts for SIT staff groups. This assignment of tasks allowed those individuals to develop a working relationship and shared understanding of the data with the scientists. However, those analysts assigned to specific task groups would have performed more efficiently had they been in

the same location as the group to which they were assigned. This would have promoted interaction, idea development, and a richer understanding of the data and analysis procedures.

The Spatial Analysis Team was ultimately responsible for all the GIS data and associated databases collected or created for the ICBEMP. The Spatial Analysis Team, however, was not in direct control of the data collection or analysis in Missoula, Wenatchee, or sites other than Walla Walla or Portland. The Landscape Ecology and Aquatic Teams were directing the data collection and analysis at these other locations. This created problems with data standards and documentation, quality control of products, and the setting of work priorities. It may have been more efficient to have all GIS analysts reporting to one Spatial Analysis Team Lead. Less time would have been spent trying to correct data and documentation or to understand analysis that had been completed by other sites.



Conclusion

Good progress has been made in building cooperation between agencies in order to implement ecosystem management. "Few, if any, activities have more comprehensive implications for the successful implementation of ecosystem management than information management: the inventory, acquisition, storage, maintenance, use, and dissemination of data and information" (FEMAT 1993). Our experience shows that information management is both possible and critical in an interagency environment. It is hoped that the documentation of information resource management methods employed by the ICBEMP and the resulting recommendations will provide a means for future efforts of a similar scope to be more effective, as well as highlight the importance of a long-term information resource management strategy for the implementation of ecosystem management.

GLOSSARY

Accuracy, Map Accuracy - The degree to which a mapped location is known to approximate an actual location. Accuracy relates to the quality of a result, and is distinguished from precision which relates to the quality of the operation by which the result is obtained.

Attribute - (n) A qualitative or quantitative non-spatial characteristic which describes a map feature. Attributes for a road might describe surface characteristics, maintenance level, width, length, etc. In the GIS environment, usually analogous to a data element or a column in a database table. (v) The process of assigning an attribute or label to a particular feature.

Cell, Grid Cell - The basic element of spatial information in a raster or grid description of spatial entities. See pixel.

Database - A collection of interrelated data stored together with a minimum of redundancy to serve multiple information needs. Generally thought of as data internally accessible to and manipulated by a computer-based system. A GIS database includes data about the spatial or locational characteristics of geographic features as well as their attributes.

Data Layer, Layer - A physical or digital separation of geographic information according to theme. In digital applications it is often used to refer to a distinct computer map file.

Data Set, Geographic Data Set - Any one of several types of data units such as a data layer (or coverage), database, or data table which can be moved, copied or manipulated as a whole distinct unit.

Derived Data - Data that result from manipulating or combining one or more data sets, as opposed to data that have been directly captured from maps, observations, or other sources.

Digitize - Conversion of any character, symbol or graphic image into computer compatible binary data. In the context of GIS, digitizing is particularly concerned with recording of spatial location of geographic phenomena in real-world coordinates, but also includes the entry of any alphabetic or numeric data which describe these phenomena. Usually accomplished by means of keyboard entry, manual tracing using a digitizing table or by optical scanning.

Domain - Same as extent.

Extent, Geographic Extent - Area of the earth covered by a digital map.

Feature, Map Feature - The map representation of a real-world phenomenon, or entity, such as a well, town, road, boundary, swamp or timber stand. Also: geographic object.

Lineage - A narrative description of the source materials from which data are derived and the methods and processes of derivation.

Manuscript - The original drawing of a map as compiled or constructed from various source data to be used in digitizing for GIS.

Metadata - Information or documentation about data. A data dictionary contains metadata (rather than the physical data itself).

Pixel - A contraction of the words picture element. A data element of a raster matrix or grid map. Equivalent to a cell.

Raster - A digital representation or display of an image or map, consisting of a regular array of rectangular pixels or cells.

Resolution - The smallest size of feature that is measured, recorded or observable, in a graphic image such as a map, or in quantifiable data. The larger the map scale, the higher the possible resolution. As map scale decreases, resolution diminishes and feature boundaries must be generalized or not shown at all. In a grid map or raster file, the cell size defines the resolution.

Scale - The relation between the distance on a photograph or a map and its corresponding distance on the ground. Scale may be expressed as a ratio, 1:24,000; a representative fraction, 1/24,000; or an equivalence, 1 in.= 2000 ft. The term "large" in "large scale" and "small" in "small scale" refers to the fraction representing the ratio of map to ground distance. For example 1:10,000 means one map unit = ten thousand ground units, and a map of that scale would be a larger scale map than one of 1:1,000,000. The larger the scale of a map, the smaller the real-world area that can be shown on a given size map, and the greater the detail that can be displayed.

Spatial Data - Data describing position or geographic location of natural and human constructed features. In this document, refers to both the locational component of geographic data and the attribute or other descriptive component.

SPUDD - Spatial Unified Data Dictionary. An Oracle database application used by the project to store and retrieve metadata information about planned and existing data sets. Developed by the Forest Service and BLM during the Forest Ecosystem Management Assessment Team (FEMAT) project.

Theme - As used by the ICBEMP, a descriptive name referring to one or more data sets indicating the specific subject matter content of the data.

Theme group - The general subject matter category of a group of themes. Used by the ICBEMP to help organize its data.

vector - 1: In statistics, a quantity whose complete description requires two or more numbers. 2: A matrix with only one row or column; its elements are referred to as components. 3: An organism that carries or transmits a pathogenic agent; *cf* carrier. 4: Any agency responsible for the introduction or dispersla of an animal or plant species [LB]

Vector Data - In GIS systems, data comprised of x-y coordinate representations of locations on the earth; taking the form of single points, strings of points (lines), or closed lines (polygons). Data are coded to express magnitude, direction, and connectivity.

Quigley, Thomas M.; Arbelbide, Sylvia J., tech. eds. 1997. An assessment of ecosystem components in the interior Columbia basin and portions of the Klamath and Great Basins. Gen. Tech. Rep. PNW-GTR-405. Portland, OR: U.S. Department of Agriculture, Forest Service, Pacific Northwest Research Station. 4 vol. (Quigley, Thomas M., tech. ed.; The Interior Columbia Basin Ecosystem Management Project: Scientific Assessment).

This paper provides detailed information about current conditions and trends for the biophysical and social systems within the basin. Social and economic conditions within the assessment area differ considerably depending to a great extent on population, diversity of employment opportunities, and changing demographics. This information can be used by land managers to develop broad management goals and priorities and provides the context for decisions specific to smaller geographic areas.

Keywords: Columbia basin, biophysical systems, social systems, ecosystem.

The Forest Service of the U.S. Department of Agriculture is dedicated to the principle of multiple use management of the Nation's forest resources for sustained yields of wood, water, forage, wildlife, and recreation. Through forestry research, cooperation with the States and private forest owners, and management of the National Forests and National Grasslands, it strives—as directed by Congress—to provide increasingly greater service to a growing Nation.

The United States Department of Agriculture (USDA) prohibits discrimination in its programs on the basis of race, color, national origin, sex, religion, age, disability, political beliefs, and marital or familial status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means of communication of program information (Braille, large print, audiotape, etc.) should contact the USDA TARGET Center at (202) 720-2600 (voice and TDD).

To file a complaint, write the Secretary of Agriculture, U.S. Department of Agriculture, Washington, DC 20250, or call (800) 245-6340 (voice), or (800) 720-1127 (TDD). USDA is an equal employment opportunity employer.
