Abstract. Wildland fires and resulting effects have increased in recent years. Efforts are under way nationwide to proactively manage vegetative conditions to reduce the threat of wildland fires. Public support is critical to the successful implementation of fuels reduction programs, particularly at the wildland–urban interface. This study examines public acceptance of fuels treatments and influencing factors in five neighbourhoods in Oregon and Utah located adjacent to public lands. Support for treatment use was high across locations. Findings suggest citizen trust in agency managers to successfully implement treatment activities is particularly influential on treatment acceptance. Thus, building and maintaining trust with local citizens is an essential element in the successful implementation of fuel management programs.

Additional keywords: fire management, social acceptance.

Introduction

Across the United States, there has been an increase in wildland fire activity and resulting effects in recent years. Since 2000, the average annual area burned has more than doubled from that of the 1990s, increasing from 1.3×10^6 to 2.8×10^6 ha (wildland fire statistics available at http://www.nifc.gov/fire_info/fires_acres.htm, accessed 5 April 2011). At the same time, a recent analysis of the wildland–urban interface (WUI), where structures and other human developments meet or intermingle with wildland vegetation, found that 9.4% of the USA land area and 38.5% of USA housing units were located in the WUI (Radeloff *et al.* 2005). Moreover, these areas are continuing to grow; a review of California, Oregon and Washington found a 17.6% growth in WUI housing units from 1990 to 2000, which is substantially higher than the 13% growth seen on all lands nationally (Hammer *et al.* 2007). This development has put an increasing number of lives and property at risk. Several recent examples are illustrative of the potential effects of WUI fires. In 2002, the Hayman Fire destroyed 600 structures in Colorado, and the Rodeo–Chediski burned another 420 structures in Arizona. Even more dramatically, during the 2003 Cedar Fire in southern California, 2400 structures were burned. These losses come despite record federal expenditures on fire suppression in recent years, a majority of which is directed at protecting private property (USDA 2006).

Not surprisingly, wildland fire policy in the USA has increasingly emphasised proactive efforts to reduce the

likelihood of fire (Stewart *et al.* 2006). These efforts consist of two primary approaches: (1) the use of fuel treatments such as prescribed fire and mechanised thinning to reduce fuel levels on public lands, and (2) encouraging property owners to take action to protect their own property. To be successful in the long run, both approaches require a supportive constituency. A growing body of research provides evidence of increasing support for the use of fuel treatments (e.g. Manfredo *et al.* 1990; Shindler and Toman 2003; Blanchard and Ryan 2007). Findings have also indicated several factors that contribute to support of agency treatments, including awareness of potential outcomes (e.g. Loomis *et al.* 2001; Brunson and Shindler 2004), citizen involvement in developing treatment plans (e.g. Winter *et al.* 2002; Blanchard and Ryan 2007), and existence of high-quality relationships between residents and agency personnel (Fleeger 2008), as well as situationally specific variables (e.g. size of treatment, proximity to homes, weather conditions; Winter *et al.* 2002).

Research has also pointed to the importance of trust in fire management agencies (e.g. Winter *et al.* 2002; Shindler and Toman 2003; Vogt *et al.* 2005). However, trust has been conceptualised and measured in different ways across this body of research. Examples include conceptualising trust as deriving from competence, care and consensual values (Winter *et al.* 2004); similarity of values, goals and views between the public and the managing agency (Winter and Cvetkovich 2008); and shared norms and values, willingness to endorse and perceived

efficacy (Liljeblad *et al.* 2009); and other studies that have drawn on Hardin's (1993) concept of 'encapsulated trust' where one party indicates their trust in another to engage in a particular action (e.g. Shindler and Toman 2003; Brunson and Evans 2005). This differentiation in the conceptualisation of trust mirrors that within the broader social science literature. In a recent review of trust-related research, Earle (2010) reviews 132 empirical studies of trust conducted between 1986 and 2009. Although this review highlights the complexity of trust research, at a general level, Earle identifies three primary approaches to conceptualising and measuring trust: (1) an emphasis on *relational trust* based on relationships between people (or between people and an organisation); (2) *calculative trust* (often referred to as confidence), which emphasises abilities and past performance; and (3) a combined approach that includes both relational and calculative items.

In this study, trust was conceptualised following this third approach and measured with two items – a general measure of trust in natural resource agencies to make good decisions about fire and fuel management and a more specific measure of participant confidence in agency managers to use particular fuel treatments. Each of these items contained both a relational (trust in natural resource managers) and calculative component (to make good decisions about fuel management or to responsibly implement treatments). Based on these measures, trust and confidence are largely treated interchangeably in the discussion that follows. Although we recognise more sophisticated measures of trust would allow a more in-depth analysis of this important concept, this study was not designed to examine the characteristics of trust but rather trust was included as one of several potential influences on acceptance of agency use of treatments.

The findings reported here build on previous research to examine the citizen acceptance of agency fuel reduction activities and influencing factors in communities at risk from wildfire effects. The study locations include five neighbourhoods in Oregon and Utah located directly adjacent to public lands. Many of the study participants owned property on the outskirts of the residential developments that shared one or more borders with publicly managed lands. Given these circumstances, the fire risk of the neighbourhoods is directly tied to that of the neighbouring public lands. The purpose of this paper is to improve our understanding of this particularly important demographic group who are the first to be affected by treatment decisions and can strongly influence the types of activities that occur on the public

land in their backyards. For this article, the study objectives were to: (1) identify current levels of acceptance of agency fuel management efforts, and (2) examine influencing factors in citizen acceptance.

Research design

The data reported here are a subset of a larger project that uses a multiple-case study design and employs qualitative and quantitative research methods to examine resident's understanding, attitudes and behaviours regarding wildfire risk and mitigation in five WUI communities in central Oregon and south-western Utah (Table 1). A case study is defined as 'an empirical inquiry that investigates a contemporary phenomenon within its real-life context' (Yin 2003, p. 13). The multiple-case study design allows analysis of property owner attitudes and behaviours towards fire and fuel management within the context of their specific location (an individual case) as well as comparisons and conclusions to be drawn across the different locations. In a multiple-case study design, cases are selected following replication and not sampling logic (Yin 2003). That is, locations are selected based on known similarities and differences in the specific context that enable a richer understanding of resulting findings by comparisons across sites.

The research team travelled to prospective study locations to meet with local agency personnel and community leaders (e.g. members of the homeowners' association board) to gain an in-depth understanding of the local fire and fuel conditions, ongoing fire mitigation programs, and accompanying public engagement activities in each location. Locations were then purposefully chosen that represented a range of different vegetation conditions, mitigation programs and engagement activities. In a multiple-case study design, the cases represent the unit of analysis (Yin 2003). For the present study, the selected neighbourhoods represent our unit of analysis, whereas our unit of observation (i.e. the unit on which data is collected) is individuals within those neighbourhoods. Following the selection of study locations, the research team worked with local community leaders to identify potential study participants. Participants were purposefully selected to represent a range of participation in fuel reduction programs, seasonal and permanent residency, and proximity to publicly managed lands.

Data for this project were collected in two phases. First, the research team met with homeowners on site and completed a structured interview following a protocol modified from

Table 1. Site characteristics

Site abbreviations are: OR A, Oregon A; OR B, Oregon B; OR C, Oregon C; UT A, Utah A; UT B, Utah B. BLM, Bureau of Land Management

Site name	Forest type	Agency responsible for nearby public lands	Parcel size (acres) (ha)	Number of existing residences	Number of participants
OR A	Ponderosa pine	Deschutes National Forest	1 (0.4)	200	40
OR B	Ponderosa pine	Deschutes National Forest	0.5 (0.2)	440	42
OR C	Lodgepole and ponderosa pine	Deschutes National Forest, Prineville BLM, Oregon Department of Fish and Wildlife	0.5–1 (0.2–0.4)	100	35
UT A	Pinyon–juniper and hardwood	Dixie National Forest, Cedar City BLM	1–2 (0.4–0.81)	70	21
UT B	Pinyon–juniper and hardwood	Dixie National Forest, Cedar City BLM	2–3 (0.81–1.21)	17	9

Nelson *et al.* (2005). The protocol consisted of a series of closed- and open-ended questions that explored the behaviours taken by homeowners to reduce their fire risk, the factors that influenced their adoption of those behaviours, and perceived outcomes of resulting treatments. In each location, the research team sent a brief cover letter to neighbourhood residents describing the project and the timeframe the team would be in the neighbourhood. One week before our visit to each location, a member of the research team called potential participants to request participation in the study and schedule an interview at the homeowner's property. Nearly all residents who were contacted expressed a willingness to participate in the study, although some were unable to owing to scheduling difficulties.

The second phase of the project consisted of a brief survey distributed to all interview participants. This survey comprised mostly closed-ended questions probing experiences and preferences regarding fire management activities on nearby public lands. The data presented here come from this second portion of the project. For these data, our primary interest was in examining the factors that influence acceptance of agency fuel reduction activities in neighbourhoods adjacent to public lands.

Building on prior research, we expected a direct association between acceptance levels and citizen perceptions of agency management, ratings of citizen–agency relationships and trust in agency managers (e.g. Winter *et al.* 2002; Shindler and Toman 2003; Blanchard and Ryan 2007; Fleeger 2008). We also expected responses would vary across locations (Manfredo *et al.* 1990; Brunson and Shindler 2004). In addition, our initial site visits and interviews with agency personnel and community leaders revealed other commonly held assumptions that the data here allow us to examine. Specifically noted was a perception that wildland fire evacuations and perceived likelihood of future fires will both lead to support for agency fuel reduction efforts, whereas newer and non-permanent residents tend to be less supportive of such treatments. The data here allow us to further examine the influence of these variables.

All reported percentages and resulting statistics come from closed-choice questions on the survey. Survey data were analysed using the *Statistical Package for the Social Sciences v. 17* (SPSS Inc., Cary, NC). To address our first objective in this paper, we first provide descriptive statistics on citizen acceptance levels and perceptions of agency management. Using correlation analysis and logistic regression, we then examine the influence of multiple variables on acceptance of both prescribed fire and mechanised thinning activities. Given our research design, such results do not allow for statistical generalisation beyond the study participants. However, findings from case-study research do provide for analytic generalisation, which Yin describes as generalisation based on comparisons with a previously developed theory (Yin 2003). Essentially, this process involves drawing on prior research to develop a description of expected influences on citizen acceptance. Findings are then compared with these expected relationships and analysed for additional evidence in support of or contrary to the expected outcomes.

Overall, 158 participants completed the on-site interview, with 148 also completing the follow-up survey (94% completion rate). As illustrated in Table 1, the study locations vary in number of developed properties. In the three Oregon locations,

the research team contacted residents until ~40 participated in the study. The Utah neighbourhoods were smaller; Utah A (UT A) had ~70 developed properties and Utah B (UT B) had fewer than 20 homes at the time of the study. In each of these neighbourhoods, a sizeable proportion of property owners, including both permanent and non-permanent residents, participated in the study (more than one-fourth in Utah A and approximately half in Utah B). Given these selection rates, we feel confident the resulting samples adequately represent the selected communities.

Site characteristics

Central Oregon

Oregon A and B (OR A and OR B) are outlying neighbourhoods of the town of Sisters (population of 1745, elevation 3200 feet (~975 m), average annual precipitation 13.62" (~346 mm)). Oregon A has 200 ~1-acre (~0.4-ha) lots, Oregon B is composed of four hundred forty 0.5-acre (~0.2-ha) forested lots; in each neighbourhood, nearly all the lots have homes or other structures on them. Forests in the area are dominated by ponderosa pine and historically experienced frequent, low-intensity fires. In both cases, these neighbourhoods are completely surrounded by forests managed by the USDA Forest Service, Deschutes National Forest, Sisters Ranger District. In the past 5 years, there have been multiple large fires nearby; in 2006, one of these fires came close enough to warrant evacuation, but did not cause any direct damage within the neighbourhoods.

Oregon C (OR C) is located outside of La Pine, Oregon (population of 1585, elevation 4235 feet (~1291 m), average annual precipitation of 11.73" (~298 mm)). The neighbourhood comprises 102 forested lots ranging from 0.5 to 1 acre (0.2 to 0.4 ha) in size; most have homes or other structures on them. The surrounding forest is a mixture of lodgepole and ponderosa pines. Lodgepole pine forests are historically characterised by high-intensity fires that tend to occur less frequently than the classic ponderosa pine fire regime. Adjacent public forests are managed by the US Department of the Interior (USDI) Bureau of Land Management (Prineville District), USDA Forest Service (Deschutes National Forest, Bend Fort Rock Ranger District), and Oregon Department of Fish and Wildlife. Although several fires have occurred in the general area in recent years, none have directly affected the neighbourhood.

Deschutes County is one of 11 counties in Oregon that is covered by the Oregon Forestland–Urban Interface Protection Act of 1997, a unique law that requires landowners in communities at high risk from wildfire to reduce vegetation around structures, along driveways and around property lines. Once work has been completed, the property is evaluated and certified. If a landowner fails to become certified, they are potentially liable for up to US\$100 000 of fire suppression costs if a fire starts on their land.

Cedar City Area, Utah

Cedar City (population 25 665, elevation 5834 feet (1778 m), average annual precipitation is 10.64" (~270 mm)) is located in south-western Utah. We selected two neighbourhoods in this area; Utah A is located just outside city limits, and Utah B is ~20 miles to the south. Nearby public lands are managed by the

Dixie National Forest and the USDI Bureau of Land Management Cedar City Field Office. The forests within and surrounding the neighbourhoods are characterised as pinyon–juniper and hardwood. The historic fire regime is complex, with some areas experiencing frequent, low-intensity fire and others characterised by high-intensity, infrequent fire (Paysen *et al.* 2000).

Utah A is located on a steep slope with 165 forested lots, ranging from 1 to 2 acres (0.4 to 0.81 ha) in size; less than half of the lots have homes or structures on them. The neighbourhood has a formal homeowner group run by elected property owners. The responsibilities of one board member are wholly dedicated to fire prevention, whereas other officers are also involved in fire safety efforts. The neighbourhood works closely with the Utah Division of Forestry, Fire and State Lands in a program that provides matching funds or assistance with chipping or removal of treated vegetation to support the creation of defensible space. At the time of this study, the neighbourhood had not been directly threatened by wildfire.

Utah B is composed of 33 forested lots, 2–3 acres (0.81 to 1.21 ha) in size; just over half have homes on them. In 2005, the neighbourhood was evacuated owing to a fast-moving, large wildfire. Although no homes were destroyed, one was damaged from radiant heat and several experienced smoke damage. Vegetation on several vacant lots and common areas was also burned. The neighbourhood does not have a formal homeowners' association. However, following the fire, neighbours began to work together to improve their fire safety. Residents in Utah B have received assistance from the Utah Division of Forestry, Fire and State Lands, particularly with chipping of removed vegetation.

Results

This section provides descriptive information regarding participants' demographic information, perceptions of forest management and management agencies, and trust in management agencies. We then present a correlation analysis of the strength of association between presented variables and acceptance of treatment programs. Last, based on the correlation results, three logistic regression models are developed to examine the relative influence of potential factors on participant acceptance of fuel treatment programs.

Site characteristics and demographic information

As noted in Table 2, nearly all the participants in three locations (Oregon A, B and Utah B) and a majority of those in OR C were

permanent residents. Just under half of participants in UT A lived on-site year round. A majority of participants were retired in each of the Oregon locations. The proportion of participants with a 4-year college degree varied from approximately half in OR A, OR C and UT A to large majorities in the other locations. In four of the locations, residents had lived in the region for ~10 years on average, whereas the median length of residency for those in UT A was only 5 years. As noted above, three of the neighbourhoods, OR A, OR C and UT B, had recently been evacuated owing to a wildland fire though no houses were lost in any of the locations. Last, participants were asked to rank the likelihood that a large wildfire would occur in their area in the next 5 years. In all locations, participants indicated a future fire was fairly likely with responses ranging from 2.63 to 3.61 on a four-point scale.

Perceptions of forest management

Participants provided some general information about their perceptions of forest management (Table 3). Large majorities rated agency management of public lands as excellent or good in each study site. A majority in each location also indicated agency managers were doing an excellent or good job in reducing the threat of wildfires. Last, participants were asked to characterise the relationship of the local forest agency with community residents. Responses to this item were quite positive; nearly all participants indicated these relationships were good or excellent.

Acceptance of fuel management on public lands

Participants were then asked to indicate the acceptability of four different methods to reduce fuel loads on public lands (mechanical thinning, mowing of understorey vegetation, herbicide application and prescribed fire – both around neighbourhoods and in remote forest areas). Responses were on a five-point scale from totally unacceptable to totally acceptable with a neutral midpoint. A 'not sure' response was also included for those who felt they did not have enough information about a specific practice to make a decision. For presentation purposes, the response categories are collapsed (e.g. 'totally' and 'some-what' responses were combined) in the tables below.

Table 4 presents responses on mechanical fuel treatments and herbicide use. Overall, mechanical thinning received the highest levels of support of all treatment options, with at least two-thirds rating it acceptable in each of the study locations. Mowing understorey vegetation was also acceptable to a majority of participants in each location, although there was less

Table 2. Site characteristics and demographic information

Percentages are significantly different at $P < 0.05$. Perceived likelihood of future fire mean rating was based on a four-point scale (from 1 = not at all to 4 = very likely). Site abbreviations are: OR A, Oregon A; OR B, Oregon B; OR C, Oregon C; UT A, Utah A; UT B, Utah B

Site	Percentage of participants permanent residents	Percentage of participants retired	Percentage of participants with a college degree	Median length of residency (years)	Recently evacuated	Perceived likelihood of future fire
OR A	97	55	47	13	Yes	3.61
OR B	100	69	64	12	Yes	3.24
OR C	59	56	53	11	No	2.63
UT A	47	33	53	5	No	3.00
UT B	100	22	100	10	Yes	3.44

certainty about this practice, with a relatively high proportion of neutral or 'not sure' responses. Notably, a substantial number of participants in UT A indicated such treatments were unacceptable, likely a reflection of the local terrain, as the steep slope made mowing impractical. Responses were substantially less positive regarding the use of herbicides. In each location, the greatest proportion of participants indicated this treatment was unacceptable whereas high numbers were also neutral or unsure about its use.

As previous research has indicated citizen support for the use of prescribed fire may be influenced by the proximity of treatments to residential areas (e.g. Winter *et al.* 2002), participants were asked to indicate their acceptance for prescribed fire

use near neighbourhoods as well as in remote forest areas (Table 5). In all but one location, a majority of participants rated prescribed fire as an acceptable management practice. Participants from UT A were the most sceptical about the use of prescribed fire; only 38% indicated such treatments were acceptable near neighbourhoods, whereas slightly more (43%) were willing to accept its use in remote areas. In the other locations, at least 57% indicated prescribed fire was an acceptable practice regardless of where it would be used. However, responses also suggest there is less agreement on the use of prescribed fire near neighbourhoods. In each study site, more participants indicated prescribed fire was unacceptable near neighbourhoods than in remote areas.

Trust in agency managers

Using a four-point scale (none, limited, moderate, full) with a 'not sure' option, participants were asked to indicate their level of trust in management agencies to make 'good decisions about wildfires and fire prevention' (Table 6). At this general level, participants expressed a high level of trust, with a majority in each location indicating they had moderate to full trust in managers in both state and federal agencies. Participants were more likely to select 'not sure' for those agencies that did not have much management presence in their area.

Participants were then asked to indicate their level of confidence in agency personnel to use specific treatments to reduce the threat of wildfire. Using the same scale as above, participants indicated their confidence in agency managers to responsibly use thinning and prescribed fire treatments (Table 7). Respondents were the most positive about thinning treatments. Nearly half expressed full confidence in agency managers, with at least another quarter indicating a moderate level of confidence to use thinning to reduce forest fuels. In each location, there was a decrease in the number of participants indicating they had full

confidence in agency managers to use prescribed fire; UT A experienced the most dramatic decrease (from 62 to 33% expressing full trust). Despite these decreases, strong majorities in each site still indicated either moderate or full confidence for prescribed fire use (ranging from 66% in UT A to 91% in OR B). For both of these treatments, there were higher levels of 'not sure' responses in the Utah sites.

Influences on treatment acceptability

Correlations

Our final objective with this paper was to examine the factors that influence treatment acceptance. We calculated bivariate correlations to assess the association between the variables reported above and acceptance of the use of thinning and prescribed fire (Table 8). For most of these variables, a Pearson's correlation coefficient was calculated. However, given the levels of measurement of some of these variables, a point-biserial correlation was used for the dichotomous independent variables 'sex', 'permanent residency' (coded 0 for seasonal and 1 for a permanent resident) and 'evacuated owing to wildfire'

Perceived likelihood of fire	−0.059 (0.489)	0.098 (0.256)	−0.044 (0.618)
Ratings of agency management	0.225 (0.010)	0.295 (0.001)	0.285 (0.001)
Trust – general	0.197 (0.022)	0.160 (0.064)	0.187 (0.033)
Treatment-specific confidence	0.500 (<0.001)	0.516 (<0.001)	0.432 (<0.001)

^APoint-biserial correlation calculated owing to dichotomous nature of independent variable.^BCramer's *V* correlation calculated owing to categorical nature of independent variable.

(coded 0 if not previously evacuated and 1 if previously evacuated). A Cramer's *V* was calculated for the categorical variables 'education' and 'location'. Values for the Pearson's and point-biserial coefficients can range from −1 to +1, with values of 0 indicating no linear association and values of +1 or −1 indicating perfect linear association. The sign of the coefficient indicates the direction of the relationship. Cramer's *V* varies from 0 to 1, with higher values representing an increased strength of relationship.

Three variables in Table 8 merit additional explanation. First, 'ratings of agency management' is an index created by combining responses to the three questions reviewed in Table 3 above (agency management of public lands, agency efforts to reduce the threat of wildfire, and past interactions with local communities); scores could vary from 0 (if the agencies were rated 'poor' on all three measures) to 9 (when receiving three ratings of 'excellent'). The next two variables represent our two measures of participant trust in agency managers. 'Trust – general' is an index variable measuring participant trust in federal and state agencies to make good decisions about wildfires and fire prevention. This index was created by combining participant trust levels (full, moderate, limited, or none) in the federal (USDA Forest Service and USDI Bureau of Land Management)

and state agencies working in the local area; scores ranged from 0 (if respondents indicated they had no trust in each agency) to 9 (for full trust). The final variable, 'treatment-specific confidence', is the more specific measure of participant confidence in agency managers to safely and effectively use thinning and prescribed fire practices (results presented in Table 7). These scores could vary from 1 (for none) to 4 (full confidence).

Variables demonstrating a significant correlation with any of the treatment types are presented in bold in Table 8. Overall, four independent variables were associated with acceptance of one or more treatments. 'Permanent residency' was significantly associated with acceptance of thinning treatments. General trust in agency managers to make good decisions about wildfire was associated with acceptance of thinning treatments as well as the use of prescribed fire in remote areas. Two variables, 'ratings of agency management' and 'treatment-specific confidence' were directly associated with all three treatments.

Logistic regression

To explore the relative influence of the variables presented here on treatment acceptability, we dichotomised responses to the acceptability questions presented in Tables 4 and 5 (with

Table 9. Logistic regression estimates predicting treatment acceptanceVariance inflation factor ≤ 1.37 for all independent variables. Variables in bold exhibit significant influence on treatment acceptance at the 0.001 level

Variable	Thinning β (significance)	Prescribed fire near neighbourhoods β (significance)	Prescribed fire in remote areas β (significance)
Permanent residency	1.425 (0.055)	0.007 (0.991)	-0.279 (0.653)
Ratings of agency management Index: 0–9 (ratings of general management, reducing threat of fire, relationship with community)	0.018 (0.198)	0.084 (0.599)	0.218 (0.179)
Trust – general Index: 0–9 (trust in state, federal agencies)	-0.225 (0.198)	-0.052 (0.705)	-0.172 (0.214)
Treatment-specific confidence	1.828 (<0.001)	1.525 (0.004)	0.990 (0.002)
Chi-square	29.239 (<0.001)	31.249 (<0.001)	18.352 (0.001)
Percentage correctly classified	88.0	74.6	77.1
Nagelkerke R^2	0.376	0.321	0.205

1 representing responses indicating the treatment is ‘somewhat’ or ‘totally’ acceptable and 0 representing all other responses – ‘somewhat’ or ‘totally’ unacceptable, ‘neutral’ and ‘not sure’). We then used logistic regression to examine the influence of four independent variables on acceptance of the use of thinning and prescribed fire close to neighbourhoods and in remote areas. Independent variables were included based on their performance in the correlation analysis; all variables that had demonstrated a significant correlation with any of the three treatments were included in the logistic regression analysis. The resulting models are presented below (Table 9).

The chi-square statistics for all three models are statistically significant, indicating the combination of independent variables in the model significantly influences treatment acceptability. Each model was also successful in classifying at least 75% of cases. Also displayed is the Nagelkerke R^2 , which provides an estimate of the variance predicted by each model (Vaske 2008); the explained variance ranges from a high of 31.2% for acceptability of prescribed fire near neighbourhood to 18.4% for the use of prescribed fire in remote areas. To test for multicollinearity among the predictor variables, we calculated the variance inflation factor (VIF). A VIF greater than or equal to 4 is generally considered to indicate a problem with multicollinearity (Vaske 2008). In our models, no variable exhibited a VIF over 1.37.

Despite the significant correlations reported in Table 8, three variables – ‘permanent residency’, ‘ratings of agency management’ and the general measure of ‘trust’ in agencies to make good decisions about fire and fuel management – did not significantly influence acceptance of thinning or prescribed fire treatments. Only the final variable, ‘treatment-specific confidence’, was significant in any of the models. Results indicate that as confidence in managers to use a specific treatment increased so did acceptance of its use. Indeed, a one-unit increase in treatment-specific confidence (i.e. from moderate to full) is predicted to increase acceptance by at least a factor of 6.2 for thinning, 4.6 for prescribed fire near neighbourhoods and 2.7 for prescribed fire in remote areas.

Discussion

Several noteworthy findings emerge from these data regarding acceptance of fuels management practices among citizens living

directly adjacent to public lands in five locations in the western USA. First, there is substantial evidence that participants in each of the study locations think highly of the federal and state managers working in their area. Although there was some variation in specific response levels, large majorities gave agency managers high ratings both for their general management efforts as well as their actions to reduce the threat of fire. Even more strikingly, nearly all participants indicated a good relationship existed between local managers and community members. Such results may be surprising given the often contentious debate surrounding many forest management decisions in recent years. Research to date has identified mixed results regarding current relationships between citizens and fire managers; although Fleeger (2008) found positive relationships between citizens and fire managers in Arizona, results from Oregon suggest such findings are not universal (e.g. Shindler and Toman 2003). What is consistent across multiple studies, however, is the importance of these relationships in citizen support of agency fuel reduction activities (e.g. Winter *et al.* 2002; Shindler and Toman 2003; Fleeger 2008).

Next, findings demonstrated relatively strong support for agency actions to actively reduce fuel loads on federal lands adjacent to participant communities. Mechanical thinning treatments received the highest support across the five study sites. A majority in each location also indicated acceptance of mowing understorey vegetation. Except in UT A, similar numbers also indicated acceptance of the use of prescribed fire both near neighbourhoods and in remote forest areas. Interestingly, acceptance of the use of prescribed fire near neighbourhoods was highest in those locations that had been most directly affected by wildfire – UT B, OR A and OR B. Only herbicides failed to receive much support; responses reflect both a lack of acceptance and a great deal of uncertainty with this potential method.

The final objective of this paper was to examine the factors that influence acceptance of treatments in the study locations. As suggested by prior literature, we expected treatment acceptance would likely vary across locations, and would be influenced by perceptions of agency management and interactions with local residents and trust in managers (e.g. Winter *et al.* 2002; Vogt *et al.* 2005; Blanchard and Ryan 2007; Fleeger 2008). We also examined other variables often assumed by managers and some community leaders, including those within

the study locations, to have a strong influence on citizen support for fuel treatments. These variables included recent evacuations due to fire events and higher perceived likelihood of future fires, both of which were assumed to positively influence treatment acceptance, whereas newly arrived and seasonal residents were presumed to exhibit lower acceptance.

Our analysis revealed very few significant associations between the potential explanatory variables and acceptance levels. Indeed, of the 11 variables examined, only four exhibited correlations significant at the 0.05 level – permanent residency, ratings of agency management, general trust in federal and state managers to make good decisions about fire and fuel management, and confidence in managers to use the specific treatment effectively. Although the correlation results provided initial support for some of the expected relationships, they failed to provide support for the expected variation across study locations. Nor was there evidence that treatment acceptance is influenced by whether participants were evacuated or the perceived likelihood of a future fire.

The further analysis of potential influencing factors through the logistic regression models also failed to provide support for three of the remaining variables – permanent versus seasonal residency, ratings of agency management and general trust in managers. Of the four variables that were significantly correlated with treatment acceptance, only one, confidence in managers to use the specific treatment, significantly influenced acceptance levels in the logistic regression models. Serving to further emphasise the importance of this specific measure of trust, this variable significantly influenced acceptance for all three treatments even after accounting for the influence of permanent residency status, ratings of agency management and general trust in managers.

Like much of the prior research on wildland fire, this study indicates trust in management agencies is a key influence on citizen support for agency management activities (e.g. Shindler and Toman 2003; Winter *et al.* 2004; Vaske *et al.* 2007). Results here also add to our understanding of this important factor by suggesting a key element of trust is that specific in managers to implement a particular management activity. Ultimately, although citizens may trust management agencies at a general level to make good decisions about wildland fire and fuel management, that general trust may not necessarily translate into trust in managers to implement specific fuel treatment activities. These findings highlight the complex nature of trust. Given the importance of this concept to citizen support for management activities, these results also emphasise the value of those efforts that have been made to date to more specifically examine the dimensions of trust in fire management (Winter *et al.* 2004; Winter and Cvetkovich 2008; Liljeblad *et al.* 2009).

Conclusion

Public acceptance is vital to successful implementation of treatments to reduce the fire risk. This is particularly true at the WUI, where local residents not only influence agency efforts to reduce fuel levels on public lands, but also play a key role in reducing overall fire risk through actions on their own property. Interestingly, despite the multiple contextual differences between locations in this study (e.g. surrounding forest type,

percentage permanent residents, recent evacuations), responses here were marked more by their commonalities than differences. To be clear, these findings do not suggest the local context is unimportant to the acceptance of fuel programs. Rather, these findings suggest certain factors, particularly trust in managers to implement specific treatments, are likely to influence treatment acceptance across locations. Just as fire and fuel management plans are based on consistent ecological principles, which are then adapted to address the specific ecological conditions at the treatment site, building and maintaining trust at the local level will require attention to the social context in each location. Residents evaluate the acceptability of agencies using treatments within their local context; thus, ratings reflect individual and social influences as well as the history of management activities in each of these locations.

Although dedicating limited resources to building and maintaining citizen trust may seem peripheral to agency objectives, doing so is important to long-term management success. Accordingly, it is important to invest in the development of such trust through engaging and working with local residents. In addition, it is important to recognise that trust is also influenced by the perceived competence and past performance of agency managers. Thus, effectively implementing management activities will not only result in the accomplishment of management objectives but can also contribute to the development of trust. As demonstrated in these locations, when such factors are in place, managers can enjoy strong support for fire and fuel management programs, even among those most directly affected by management activities.

Acknowledgements

The authors acknowledge the USDA Forest Service Northern Research Station for providing funding for this project and the Joint Fire Science Program for providing additional support. The authors also express thanks to Jim Bennett, Stacey Sargent Frederick, Angela Mallon and Patrick Shannon for their help with data collection as well as to all the property owners who participated in this study.
