Forest Statistics for Southwest Louisiana Parishes

Arnold Hedlund
and
J. M. Earles

Southern Forest Experiment Station
New Orleans, Louisiana
Forest Service, U. S. Department of Agriculture

1974

This report tabulates information from a new forest inventory of parishes in south-western Louisiana. The tables are intended for use as source data in compiling estimates for groups of parishes. Because the sampling procedure is designed primarily to furnish inventory data for the State as a whole, estimates for individual parishes have limited and variable accuracy.

The data on forest acreage and timber volume were secured by a systematic sampling method involving a forest-nonforest classification on aerial photographs and on-the-ground measurements of trees at sample locations. The sample locations were at the intersections of a grid of lines spaced 3 miles apart. At each forested location, 10 small plots were uniformly distributed on an area of about 1 acre.

The sampling errors to which the parish area and volume totals are liable (on a probability of two chances out of three) are shown in table 1.

Table 1. *Sampling errors¹ for forest land and timber volume, 1974*

Parish	Commercial forest land	Growing stock	Saw- timber
--- Percent ---			
Allen	2	10	15
Beauregard	1	8	13
Calcasieu	1	16	19

Natchitoches	1	6	9
Rapides	2	9	11
Sabine	2	7	10
Vernon	1	7	9
All parishes	0.5	2.7	3.7

¹ By random sampling formula.

An approximation of sampling errors for groups of parishes may be obtained by using the formula:

$$e = \frac{(SE) \sqrt{\text{specified volume or area}}}{\sqrt{\text{volume or area total in question}}}$$

Where: e = Estimated sampling error of the volume or area total in question

SE = Specified sampling error for the State.

The error decreases when data for two or more parishes are grouped. Conversely, as data for individual parishes are broken down by various subdivisions, the possibility of error increases and is greatest for the smallest items. Sampling errors associated with the estimates of the principal timber species in this report are shown in table 2.

Because of differences in standards of tree measurement, direct comparisons cannot be made between the estimates in this report and

Table 2. *Sampling errors for timber volume by species, 1974*

Species	Growing stock	Sawtimber
- Percent -

All species	+ 22

¹ Based on current measurement standards.

² Negligible.

Data for other parishes of Louisiana will be published as field work progresses. A State-wide interpretive report will be issued when all parishes have been inventoried; it will include an evaluation of timber trends since 1964.

DEFINITIONS OF TERMS

Acceptable trees.—Growing-stock trees of commercial species that meet specified standards of size and quality but do not qualify as desirable trees.

Commercial forest land.—Forest land producing or capable of producing crops of industrial wood and not withdrawn from timber utilization.

Desirable trees.—Growing-stock trees that are of commercial species, have no defects in quality for

timber products, are of relatively high vigor, and contain no pathogens that may result in death or serious deterioration before rotation age.

Forest type.—A classification of forest land based upon the species forming a plurality of live-tree stocking.

Growing-stock trees.—Live trees that are of commercial species and qualify as desirable or acceptable trees.

Growing-stock volume.—Net volume in cubic feet of growing-stock trees at least 5.0 inches in diameter at breast height, from a 1-foot stump to a minimum 4.0-inch top diameter outside bark of the central stem, or to the point where the central stem breaks into limbs.

Physiographic site.—A classification of forest land according to its suitability for growing certain species groups—pines, upland hardwoods, or bottomland hardwoods.

Poletimber trees.—Growing-stock trees of commercial species at least 5.0 inches in diameter at breast height, but smaller than sawtimber size.

Sawtimber trees.—Live trees that are of commercial species, contain at least a 12-foot saw log, and meet regional specifications for freedom from defect. Softwoods must be at least 9.0 inches in diameter at breast height and hardwoods at least 11.0 inches.

Sawtimber volume.—Net volume of the saw-log portion of live sawtimber in board feet, International ¼-inch rule.

Site class.—A classification of forest land in terms of inherent capacity to grow crops of industrial wood.

Stand-size class.—A classification of forest land based on the size class of growing-stock trees on the area; that is, sawtimber, poletimber, or seed lings and saplings.
